 at ord. temp. (Berthelot, C. R. 1897, 125.  
 749.)

$\text{H}_2\text{SO}_4$  attacks only when hot and conc.

 $\text{Hg}$  either with or without air. (Pitman, J.  
 Am. Chem. Soc. 1898, 20. 100.)

$\text{H}_2\text{SO}_4$  attacks  $\text{Hg}$  at  $20^\circ$  if it contains

 the dark. (Bailey, Chem. Soc. 1888, 53. 759.)

 ence of  $\text{Mn}(\text{NO}_3)_2$  or  $\text{NaNO}_2$ . (Ray, Chem.  
 Soc. 1911, 39. 1015.)

 is absent. (Veley, B. 1895, 28. 928.)

Easily sol. in soluble iodides +  $\text{Aq}$ . More sol. in hot than in cold  $\text{NaI}$  or  $\text{KI} + \text{Aq}$ . When conc., 1 mol.  $\text{KI}$  in hot solution dissolves 3 mols.  $\text{HgI}_2$ , but a portion separates on cooling.  $\text{BaI}_2$ ,  $\text{SrI}_2$ ,  $\text{MgI}_2$ , and  $\text{CaI}_2$  act in the same way. Easily sol. in cold, more sol. in hot  $\text{ZnI}_2 + \text{Aq}$ , 2 mols.  $\text{HgI}_2$  being dissolved to 1 mol.  $\text{ZnI}_2$ . In  $\text{NH}_4\text{I} + \text{Aq}$ , 3 mols.  $\text{HgI}_2$  are dissolved to 2 mols.  $\text{NH}_4\text{I}$ . Abundantly sol. in hot  $\text{KCl}$ ,  $\text{NaCl}$ ,  $\text{NH}_4\text{Cl} + \text{Aq}$ , but separates out on cooling, and the trace remaining may be pptd. by  $\text{H}_2\text{O}$ , 2 g.  $\text{KCl}$  in solution dissolves 1.166 g.  $\text{HgI}_2$ . **Nitric acid,  $\text{HNO}_3$ .**

Miscible with  $\text{H}_2\text{O}$ . When  $\text{HNO}_3 + \text{Aq}$  distilled at 760 mm. pressure, an acid containing 68%  $\text{HNO}_3$  is formed, which boils at  $120.5^\circ$  under 735 mm. pressure. By distilling at 150 mm. pressure the acid contains 67%  $\text{HNO}_3$ ; at 70 mm. (b.-pt.  $65-70^\circ$ ) the acid contains 66.7%  $\text{HNO}_3$ . The percentage of  $\text{HNO}_3$  in the liquid obtained by passing air into  $\text{HNO}_3 + \text{Aq}$  containing 64-68%  $\text{HNO}_3$  varies with the temp.; the higher the temp. the greater the percentage of  $\text{HNO}_3$ . (Bunsen, Chem. Soc. 13. 150.)

$\text{HNO}_3 + \text{Aq}$ of 1.51	sp. gr. contains 67% $\text{HNO}_3$

For sp. gr. of HNO<sub>3</sub>+H<sub>2</sub>SO<sub>4</sub>, see under  
H<sub>2</sub>SO<sub>4</sub>.

Partition coefficient for HNO<sub>3</sub> between  
ether and H<sub>2</sub>O is increased by the addition  
of nitrates. (Tanret, C. R. 1897, 124. 464.)

The hydrates described by Erdmann do  
not exist. There are only two authentic hy-  
drates, the mono- and the tri-hydrate.  
(Küster, Ch. Z. 1904, 28. 132.)

The composition of the hydrates formed  
by HNO<sub>3</sub> at different dilutions is calculated  
from determinations of the lowering of the  
fr.-pt. produced by HNO<sub>3</sub> and of the con-  
ductivity and sp. gr. of HNO<sub>3</sub>+Aq. (Jones,  
Am. Ch. J. 1905, 34. 328.)

**Dinitric acid**, H<sub>2</sub>N<sub>2</sub>O<sub>11</sub>=2N<sub>2</sub>O<sub>5</sub>, H<sub>2</sub>O.

Fumes on air. Miscible with H<sub>2</sub>O, with  
evolution of much heat. (Weber, J. pr. (2)  
6. 342.)

**Nitrates.**

All nitrates are sol. in H<sub>2</sub>O except a few  
basic compounds. Most nitrates are insol. in

conc.  $\text{HNO}_3 + \text{Aq}$ ; many are sol. in alcohol; some are sol. in glycerine.

**Aluminum nitrate, basic,  $2\text{Al}_2\text{O}_3, 3\text{N}_2\text{O}_5 + 3\text{H}_2\text{O}$ .**

Sol. in  $\text{H}_2\text{O}$ . (Ordway, Sill. Am. J. (2) 26. 203.)

Basic aluminum nitrates containing 2 mols. or less of  $\text{Al}_2\text{O}_3$  to one of  $\text{N}_2\text{O}_5$  may be obtained sol. in  $\text{H}_2\text{O}$ , but the compounds containing more than 2 mols.  $\text{Al}_2\text{O}_3$  are insol. in  $\text{H}_2\text{O}$ . (Ordway, l. c.)

$2\text{Al}_2\text{O}_3, \text{N}_2\text{O}_5 + 10\text{H}_2\text{O}$ . (Ditte, C. R. 110. 782.)

$\text{Al}_2\text{O}_3 \cdot \text{H}_2\text{O}, \text{HNO}_3$ . Sol. in  $\text{H}_2\text{O}$ . (Schlumberger, Bull. Soc. 1895, (3) 13. 59.)

**Aluminum nitrate,  $\text{Al}(\text{NO}_3)_3 + 9\text{H}_2\text{O}$ .**

Deliquescent. Very sol. in  $\text{H}_2\text{O}$ ,  $\text{HNO}_3 + \text{Aq}$ , or alcohol. (Berzelius.)

Melts in its crystal  $\text{H}_2\text{O}$  at  $72.7^\circ$ . (Ordway.)

Sol. in 1 pt. strong alcohol. (Wenzel.)

Difficultly sol. in acetone. (Naumann, B. 1904, 37. 4328.)

Insol. in ethyl acetate. (Naumann, B. 1910, 43. 314.)

**Ammonium nitrate,  $\text{NH}_4\text{NO}_3$ .**

Deliquescent.

Sol. in 0.502 pt.  $\text{H}_2\text{O}$  at  $18^\circ$ . (Karsten.)

**Ozone,  $\text{O}_3$ .**

Not appreciably sol. in  $\text{H}_2\text{O}$ . (Schönbein.)  
Imparts its taste and properties to  $\text{H}_2\text{O}$ .  
(Williamson.)

Later, Carius (B. 5. 520) found that 1000  
vols.  $\text{H}_2\text{O}$  at  $1-2.5^\circ$  absorb 5.11 vols.  $\text{O}_3$  (red.  
to  $0^\circ$  and 760 mm.). He also still later (A.  
174. 1) found, by conducting the gas for 9-12  
hours through  $\text{H}_2\text{O}$ , that 1000 vols.  $\text{H}_2\text{O}$   
absorb a maximum of 28.160 vols.  $\text{O}_3$ . The  
ozone oxygen used contained 3.44 vols.  $\text{O}_2$   
in 100 vols.  $\text{O}_3$ . Since gases are absorbed in  
proportion to their partial pressure, which is  
very small for the  $\text{O}_3$ , the amount of absorp-  
tion of water for the gas is very considerable.  
Carius calculated the coefficient of absorption  
at  $+1^\circ$  to be 0.834.

Ozone is *not at all* absorbed by  $\text{H}_2\text{O}$ ; the  
 $\text{H}_2\text{O}$  through which ozone had been passed  
gave no reactions for ozone. (Rammelsberg,  
B. 6. 603.)

Schöne (B. 6. 1224) corroborates Carius,  
and finds 8.81 vols. to 1000 vols.  $\text{H}_2\text{O}$  as a  
maximum amount absorbed.

Sol. in  $\text{H}_2\text{O}$ . (Leeds, B. 12. 1831.)

Calcium orthophosphate,  $Ca_3(PO_4)_2$ .

Decomp. by long boiling with  $H_2O$  into basic salt,  $3Ca_3(PO_4)_2, CaO, H_2O$ . This decomp. begins with cold  $H_2O$ , so that the solubility at 6-8° varies from 9.9 to 28.6 mg. in a litre. (Warrington, Chem. Soc. (2) 11. 983.)

1 l. cold  $H_2O$  dissolves in 7 day ignited, and 79 mg. freshly pre  $Ca_3(PO_4)_2$ . (Völcker, J. #### Calcium tetrahydrogen orthophosphate, $\text{CaH}_4(\text{PO}_4)_2$ + $\text{H}_2\text{O}$ .

Very deliquescent. Crystals take up 97.7  
pts.  $\text{H}_2\text{O}$  in 16 days, and 226 pts.  $\text{H}_2\text{O}$  in 28  
days from air saturated with moisture.  
(Birnbbaum, Zeit. Ch. (2) 7. 131.)

Not hygroscopic when pure. (Stocklassa,  
B. 23. 626 R.)

Completely sol. in 100 pts.  $\text{H}_2\text{O}$ , but de-  
comp. by 10–40 pts.  $\text{H}_2\text{O}$  with separation of  
 $\text{CaHPO}_4$ , which slowly dissolves. (Erlen-  
meyer, J. B. 1873. 254.)

Later (B. 9. 1839) Erlenmeyer says  
 $\text{CaH}_4(\text{PO}_4)_2$  +  $\text{H}_2\text{O}$  is sol. in 700 pts.  $\text{H}_2\text{O}$  and  
decomp. into  $\text{CaHPO}_4$  by a less amount of  
 $\text{H}_2\text{O}$ . Wattenberg (Z. anal. 19. 243) says that  
the decomposition by small amts. of  $\text{H}_2\text{O}$   
down to 144 pts.  $\text{H}_2\text{O}$  to 1 pt. salt is inappre-  
ciable.

Completely sol. in 200 pts.  $\text{H}_2\text{O}$  if pure, and  
in less  $\text{H}_2\text{O}$  in presence of  $\text{H}_2\text{PO}_4$ . (Stocklassa.)

Sol. in 25 pts.  $\text{H}_2\text{O}$  at 15°. Solution begins  
to decompose when warmed to 50°. (Otto,  
C. C. 1887. 1563.)

Greatly decomp. by  $\text{H}_2\text{O}$  and the resulting  
solution is to be regarded as a solution of the  
decomposition products rather than of the  
substance itself. The presence of an excess  
of  $\text{CaSO}_4$  does not materially affect the  
amount of phosphoric acid entering the solu-  
tion. (Cameron, J. Am. Chem. Soc. 1904, 26.  
1462.)

Violently decomp. by  $\text{H}_2\text{O}$  in conc. solu-  
tion; only sl. decomp. when dissolved in 200  
pts.  $\text{H}_2\text{O}$ . (Stocklassa, Z. anorg. 1892, 1. 310.)

Pt.

acked by H<sub>2</sub>O, H<sub>2</sub>SO<sub>4</sub>, HCl, or l. Slowly sol. in aqua regia, or a HBr and HNO<sub>3</sub>, but much less Au.

sted Pt is remarkably sol. in n presence of air. (Wilm, B. 1881,

foil is attacked by fuming HCl ence of light, but not in the dark. C. R. 1904, **138**. 1297.)

l+Aq dissolves 10-15% Pt from lack. (Wöhler, B. 1903, **36**. 3482.) NO<sub>2</sub> oxidizes Pt black; Pt sponge, sheet Pt, slightly. (Wöhler, **31**.)

essence of Hg is more or less sol. NO<sub>2</sub>. (Tarugi, Gazz. ch. it. 1903, )

ls are attacked by evaporating rein. (Jaunek and Meyer, Z. **3**, **83**. 71.)

in conc. H<sub>2</sub>SO<sub>4</sub> containing small of nitrogen oxides. (Scheurer- R. **86**. 1082.)

pptd. by formic acid, is easily ling H<sub>2</sub>SO<sub>4</sub>. (Deville and Stas, )

et Pt is attacked by boiling H<sub>2</sub>SO<sub>4</sub> K<sub>2</sub>SO<sub>4</sub>; 1 sq. cm. loses 0.01 g. and velocity of the reaction is not by addition of HNO<sub>3</sub>. Pt black ly dissolved under the above con- 50 hours. (Delépine, C. R. 1905,

data on solubility of Pt in H<sub>2</sub>SO<sub>4</sub> by Delépine. (C. R. 1906, **142**.

HCl+HNO<sub>3</sub>, so long as they are sufficiently dil. or the temperature is so low that they cannot react on each other, have no action on Pt. Addition of Cl does not bring about reaction, but a few drops of KNO<sub>3</sub> or N<sub>2</sub>O<sub>5</sub>+Aq bring about an immediate reaction. (Millon.)

Slowly sol. in HI+Aq. (Deville, C. R. **42**. 896.)

Conc. H<sub>3</sub>PO<sub>4</sub> attacks Pt when heated in presence of air, but not in its absence. (Hüttner, Z. anorg. 1908, **59**. 216.)

Pt dissolves easily in most acids when they contain H<sub>2</sub>O<sub>2</sub>. (Fairley, B. 1875, **8**. 1600.)

Slowly sol. in boiling FeCl<sub>3</sub>+Aq. (Saint-Pierre, C. R. **54**. 1077.)

FeCl<sub>3</sub> in acid solution is without influence on Pt. (Marie, C. R. 1908, **146**. 476.)

Pt is completely insol. in KCN+Aq. (Rössler, Z. Chem. **1866**. 175.)

Pt is attacked by boiling conc. KCN+Aq. (Deville and Debray, C. R. **82**. 241.)

Solubility of Pt in 10% KCN+Aq is very small at ord. temp. (1.4 mg. in 8 days) but is considerably greater in boiling conc. KCN+Aq. (71.5 mg. in 5 hours). (Glaser, Z. Elektrochem. 1903, **9**. 15.)

Pt foil is dissolved in boiling KCN+Aq (0.030 g. for 1 cc. in 1 hour). Insol. in cold KCN+Aq. (Brochet and Petit, C. R. 1904, C. R. **138**. 1255.)

Sol. in RbCl<sub>4</sub>I+Aq. (Erdmann, Arch. Pharm. 1894, **232**. 30.)

Insol. in liquid NH<sub>3</sub>. (Gore, Am. Ch. J. 1898, **20**. 828.)

1000 pts.  $CS_2$  dissolve 1 pt. cryst. Se at boiling-point ( $46.6^\circ$ ), and 0.16 pt. at  $0^\circ$  (Mitscherlich, J. B. 1855. 314.) Solubility of Se in  $CS_2$  is variable—1 pt. Se is sol. in 1376–2464–3746 pts.  $CS_2$  at  $20^\circ$  (Rammelsberg, B. 7. 669). Cryst. Se, which is sol. in  $CS_2$ , becomes insol. in  $CS_2$  after heating to  $110^\circ$ , but after fusion is again sol. (Otto).

Four modifications.—(1) Amorphous red; (2) crystalline red; (3) granular gray; (4) laminated. 1 and 2 are sol. in  $CS_2$ , 3 and 4 are insol. in  $CS_2$ . All forms are sol. in  $SeCl_2$ , from which crystallizes a black modification, insol. in  $CS_2$ .  $CCl_4$  with trace of  $CS_2$  dissolves red Se slightly, black Se not at all.  $Se(C_2H_5)_2$  dissolves all modifications in small but apparently equal quantities. (Rathke, A. 162. 181.)

According to Saunders (J. phys. Chem. 1900, 4. 428) selenium exists in three modifications.

Sol. in  $CSe_2$ , ethyl selenide, and in ethyl sulphide.

Very sol. in  $Se_2Cl_2$ . (Rathke, A. 1869, 162. 181.)

Completely sol. in  $CS_2$  at ord. temp. if Se has not been heated. If heated or extracted with warm  $CS_2$  it becomes partly insol. (Peterson, Z. phys. Chem. 1891, 81. 612.)

Passes into red crystalline form in solution in  $CS_2$ ,  $C_4H_8$ , isobutyric acid, acetophenone, acetone,  $CHCl_3$ , thiophene, toluene, benzonitrile, ethyl acetate, and alcohol. (Saunders, J. phys. Chem. 1900, 4. 463.)

Solution in quinoline, aniline, pyridine,

etc., cause conversion into gray or form.

**c. Colloidal.**

Forms colloidal solution with  $H_2O.$

A colloidal solution of Se in  $H_2O$  is obtained. It is not decomp. by boiling is decomp. by electrolytes with separated selenium. (Gutbier, Z. anorg. 19106.)

**Sesquihydrauramine**,  $(HOAu)_2N, NH_3$ .

See *Sesquihydrauramine*.

**Silicic acid**,  $SiO_2, zH_2O$ .

See also *Silicon dioxide*.

Silicic acid is sol. in 1000 pts. pure  $H_2O$ . (Kirwan.)

When pptd. from alkali silicates +  $Aq$  by  $CO_2$ , 0.021 pt.  $SiO_2$  remains dissolved in 100 pts.  $H_2O$ . (Struckmann, A. **94**. 341.)

When pptd. as above, 100 pts.  $H_2O$  dissolve 0.09 pt.  $SiO_2$  in 3 days; 100 pts.  $H_2CO_3 + Aq$  dissolve 0.078 pt.  $SiO_2$  in 3 days. But if heated much more dissolves, the jelly itself becoming liquid, such jelly containing 2.49 pts.  $SiO_2$  to 100 pts.  $H_2O$ . This solution is not pptd. by considerable quantities of alcohol, but conc.  $(NH_4)_2CO_3$ ,  $NaCl$ , or  $CaCl_2 + Aq$ , etc., cause gelatinization. (Maschke, J. pr. **68**. 234.)

Solubility in  $H_2O$  depends on the amt. of  $H_2O$ , in presence of which the silicic acid is set free by dil. acids,  $CO_2$ , or alkali salts +  $Aq$ . If  $H_2O$  is present in sufficient quantity to retain the silicic acid, much more will remain in solution than can be dissolved by digesting the gelatinous acid with  $H_2O$  afterwards. 1 pt.  $SiO_2$  can thus be held in solution by 500 pts.  $H_2O$ . Presence of  $NH_4OH$ ,  $(NH_4)_2CO_3$ , or  $NH_4Cl$  (in solutions of which  $SiO_2$  is remarkably insol.) diminishes the power of  $H_2O$  to retain  $SiO_2$  in solution.  $SiO_2$  is always more sol. in dil. than conc.  $NH_4OH + Aq$ . (Liebig, A. **94**. 373.)

Silicic acid from the coagulation of the colloidal form (see p. 802) is sol. in about 5000 pts.  $H_2O$  when formed from a 1% solution, and 10,000 pts. when formed from a 5% solution, but is insol. after being dried. (Graham, A. **121**. 36.)

Silicic acid is more sol. in dil. acids than in  $H_2O$ , because, when acid is added in excess to moderately dil.  $K_2SiO_3 + Aq$ , the solution remains clear, but if only enough acid is added to neutralize the base present, silicic acid will gradually separate out. If acid is added to conc.  $K_2SiO_3 + Aq$ , silicic acid separates out insol. in excess of acid, but if 20-30 pts.  $H_2O$  are present to 1 pt.  $K_2SiO_3$ , and an excess of acid added at once, the silicic acid will remain in solution. This result is obtained with  $HCl$ ,  $HNO_3$ ,  $H_2SO_4$ , or

$\text{HC}_2\text{H}_3\text{O}_2 + \text{Aq.}$  These solutions may dissolve a neutral salt until saturated and no silicic acid will separate out. Therefore it is the acid that holds the  $\text{SiO}_2$  in solution, and not the  $\text{H}_2\text{O}$ . (C. J. B. Karsten, (1826) Pogg. 6. 353.)

Even  $\text{CO}_2$  has the power of holding  $\text{SiO}_2$  in solution. (Karsten, *l. c.*)

Solubility in acids of silicic acid of Struckmann (*see above*): 100 pts. dil.  $\text{HCl} + \text{Aq}$  of 1.088 sp. gr. dissolve 0.0172 g.  $\text{SiO}_2$  in 11 days; 100 pts.  $\text{H}_2\text{O}$  sat. with  $\text{CO}_2$  dissolve 0.0136 g.  $\text{SiO}_2$  in 7 days.

Silicic acid obtained by passing  $\text{SiF}_4$  into  $\text{H}_2\text{O}$  is sol. while still moist in 11,000 pts. cold, and 5500 pts. boiling  $\text{HCl} + \text{Aq}$  of 1.115 sp. gr. (Fuchs, A. 82. 119.)

Silicic acid at the moment of separation (as in dissolving cast-iron, steel, etc.) is abundantly sol. in aqua regia (3 pts.  $\text{HCl} + \text{Aq}$  of sp. gr. 1.13 and 1 pt.  $\text{HNO}_3 + \text{Aq}$  of sp. gr. 1.33). (Wittstein, Z. anal. 7. 433.)

The aq. solution obtained by the hydrolysis of ethyl silicate is more stable in acids +  $\text{Aq}$  or alkali than in pure  $\text{H}_2\text{O}$ . (Jordis, Z. anorg. 1903, 35. 16.)

$\text{NH}_4\text{OH} + \text{Aq}$  dissolves considerable freshly precipitated silicic acid,  $(\text{NH}_4)_2\text{CO}_3$  only a very little. (Karsten, Pogg. 6. 357.)

Dry or ignited  $\text{SiO}_2$  is sol. in  $\text{NH}_4\text{OH} + \text{Aq}$ . 100 pts.  $\text{NH}_4\text{OH} + \text{Aq}$  containing 10%  $\text{NH}_3$  dissolve: 0.714 pt.  $\text{SiO}_2$  from gelatinous silicic acid; 0.303 pt. from artificially dried silicic acid; 0.377 pt. from amorphous  $\text{SiO}_2$ ; 0.017 pt. from quartz. (Pribram, Z. anal. 6. 119.)

$\text{NH}_4\text{OH} + \text{Aq}$  dissolves 0.382 pt.  $\text{SiO}_2$  from dry silicic acid; 0.357 pt. from ignited  $\text{SiO}_2$ ; 0.00827 pt. from quartz. (Souhay, Z. anal. 11. 182.)

Silicic acid precipitated from alkali silicates +  $\text{Aq}$  with  $\text{CO}_2$  is sol. as follows: 100 pts. pure  $\text{H}_2\text{O}$  dissolve 0.021 pt.  $\text{SiO}_2$ ; 100 pts.  $(\text{NH}_4)_2\text{CO}_3 + \text{Aq}$  containing 5%  $(\text{NH}_4)_2\text{CO}_3$ , 0.020 pt.; 100 pts. containing 1%  $(\text{NH}_4)_2\text{CO}_3$ , 0.062 pt.; 100 pts.  $\text{NH}_4\text{OH} + \text{Aq}$  containing 19.2%  $\text{NH}_3$ , 0.071 pt.; 100 pts. containing 1.6%, 0.0986 pt. (Struckmann, A. 94. 341.)

100 pts.  $\text{NH}_4\text{OH} + \text{Aq}$  (10%  $\text{NH}_3$ ) dissolve of: crystallised  $\text{SiO}_2$ , 0.017 pt.; amorphous  $\text{SiO}_2$ , ignited, 0.38 pt.; amorphous  $3\text{SiO}_2 \cdot 4\text{H}_2\text{O}$ , 0.21 pt.; amorphous silicic acid in form of jelly, 0.71 pt. Upon evaporation no ppt. is formed, even when 80 mols.  $\text{SiO}_2$  are present to 1 mol.  $\text{NH}_3$ . (Wittstein, J. B. 1866. 192.)

Sol. in  $\text{KOH}$  or  $\text{NaOH} + \text{Aq}$ , especially if warm. (Dumas.)

Sol. in  $\text{K}_2\text{SiO}_3$  or  $\text{Na}_2\text{SiO}_3 + \text{Aq}$ . (Fuchs.)

Easily sol. in boiling  $\text{Na}_2\text{CO}_3 + \text{Aq}$ , separating as a jelly on cooling. (Pfaff.)

$\text{NH}_4\text{Cl}$  or other  $\text{NH}_4$  salts ppt.  $\text{SiO}_2$  from solution in  $\text{Na}_2\text{CO}_3 + \text{Aq}$ .

100 pts.  $\text{Ti}_2\text{O}_3$  in  $\text{H}_2\text{O}$  dissolve 4.17 pts. amorphous  $\text{SiO}_2$  in 24 hours' boiling. (Flemming, Jena. Zeit. 4. 36.)

Sol. in butyl amine. (Wurtz, A. d. 166.)

Not more sol. in  $\text{H}_2\text{O}$  containing  $\pi$  in pure  $\text{H}_2\text{O}$ . (Petsholdt, J. pr. 60.)

#### Soluble silicic acid.

*Colloidal form by dialysis.* Sol. containing 4.9%  $\text{SiO}_2$  may be evaporated they contain 14%  $\text{SiO}_2$ . The  $\text{SiO}_2$  is from its solution thus made in man.

(1) By standing. This happens easily the more conc. the solution hastened by heat. A 10–12% solution is at ordinary temp. in a few h immediately upon heating. A 5–6% may be kept 5–6 days, a 2% solution months, and a 1% solution may or more years without gelatinizing.

(2) When the solution is evaporated in vacuo at 15° a transparent jelly which is insol. in  $\text{H}_2\text{O}$ .

(3) The coagulation of colloidal is accelerated by powdered graphite indifferent bodies, and it is brought few minutes by a solution of the borates, even when only  $\frac{1}{10,000}$  carbonate is present. (Graham, A.)

(4) Coagulation is also brought passing  $\text{CO}_2$  through the solution.

$\text{CO}_2$  does not cause coagulation.

Coagulation is not caused by  $\text{HNO}_3$ ,  $\text{HC}_2\text{H}_3\text{O}_2$ ,  $\text{H}_2\text{C}_2\text{H}_3\text{O}_4$ , or  $\text{Aq}$ , or by neutral or acid salts + ham.)

$\text{NaCl}$  and  $\text{Na}_2\text{SO}_4 + \text{Aq}$  coagulation. (Maschke.)

Alcohol, sugar, glycerine, or not coagulate.

Soluble  $\text{Al}_2\text{O}_3\text{H}_3$ ,  $\text{Fe}_2\text{O}_3\text{H}_3$ , all casein precipitate soluble  $\text{SiO}_2$ . (121. 36.)

The jelly from colloidal  $\text{SiO}_2$  is slightly alkaline  $\text{H}_2\text{O}$ . 1 pt.  $\text{NaO}$  pts.  $\text{H}_2\text{O}$  dissolves in an hour at 1 of the jelly corresponding to 20 (Graham.)

#### Other colloidal forms.

Various solutions of silicic acid obtained as follows:

The jelly formed when  $\text{SiF}_4$  through  $\text{H}_2\text{O}$  dissolves in a large  $\pi$  and  $\text{SiO}_2$  separates out on evaporation is still sol. in  $\text{H}_2\text{O}$ , but is made insol. on evaporation with  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$ . (Be)

When  $\text{SiF}_4$  is absorbed by  $\text{H}_2\text{BO}_3$ , and the  $\text{HF}$  and  $\text{H}_2\text{BO}_3$  a large excess of  $\text{NH}_4\text{OH} + \text{Aq}$  is obtained which is very sol. in solution is not decomp. by boil evaporation an insol. powder remains. (A. ch. 14. 366.)

When  $\text{K}_2\text{SiO}_3 + \text{Aq}$  is precipitated the precipitate washed and dissolved in  $\text{Aq}$ , the solution treated with  $\text{H}_2\text{S}$  (boiled), a solution of silicic acid

ses with KOH or  $\text{NH}_4\text{OH} + \text{Aq.}$  (3) 21. 40.)

$\text{O}_2 + \text{Aq}$  containing at most 3% ted with  $\text{HCl} + \text{Aq}$  of 1.10 sp.  $\text{O}_2$  added until the solution is cent and carefully warmed to us mass is obtained which will  $\text{O}$  by 12–16 hours' boiling if being exposed to the air. The htly opalescent. The solution ated by heat until it contains a vacuum or over  $\text{H}_2\text{SO}_4$ , solu- g 10% may be obtained. The it, freezing, alcohol, or  $\text{H}_2\text{SO}_4$ , coagulate the solution. (Kühn,

$\text{O}_2$  gives off  $\text{H}_2\text{S}$ , and forms a  $\text{O}_2$  which, after dilution, can be hs. But when boiled or evapo- n a sol. silicate is added, it tinous. It leaves an insol. vaporated to dryness. (Freymy, 314.)

ns of silicic acid have been de- nite compounds of  $\text{SiO}_2$  with nts of  $\text{H}_2\text{O}$ , but it is doubtful if ite compounds exist, as the per- ) varies with the moisture of the is exposed. (See Ebelmen, A. 9; Doveri, A. ch. (3) 21. 40; 19; Merz, J. pr. 99. 177; van 11. 2232, etc.)

Above compounds are all more or less indefinite.

*Water glass.*  $xNa_2O, ySiO_2, zH_2O$ . Sol. in  $H_2O$ , but solution is decomposed by all weak acids, even  $CO_2$ .

Fused water glass is but little acted on by cold  $H_2O$ , but when pure, easily dissolves in  $H_2O$  by long boiling. (Ordway, Am. J. Sci. (2) 32. 337.)

When the  $SiO_2$  is present in greater proportion than in  $Na_2O, 3SiO_2$ , it is very difficult to dissolve in  $H_2O$ .

Na silicate is less easily sol. in  $H_2O$  than the corresponding K compound.

Solubility of water glass in  $H_2O$  is much impaired by earthy impurities, so that these have great effect in preventing the solubility.

$NH_4$  salts decomp. water glass solutions. A solution containing  $\frac{1}{2}\%$   $Na_2SiO_3$  is scarcely precipitated by  $NH_4Cl$ , but easily by  $NH_4NO_3$ . (Fluckinger.)

Precipitated by  $NH_4OH + Aq$  as  $Na_2SiO_3$ .

Many sodium and potassium salts, especially the chlorides and acetates, form precipitates in solutions of water glass; these precipitates are larger the more concentrated the solution is, and the greater amount of  $SiO_2$  it contains. Heating hastens the precipitation by chlorides, nitrates, and sulphates, but delays that by acetates.  $KOH + Aq$  does not precipitate.

Cold sat.  $Na_2SO_4 + Aq$  does not precipitate even on heating, but 1 pt. anhydrous  $Na_2SO_4$  dissolved in 2 pts.  $H_2O$  precipitates a hot solution of  $Na_2SiO_3$ .

(a) *Crystalline*. Min. Quartz, Tridymite.  
Insol. in  $\text{H}_2\text{O}$ , and acids, except HF.  
Sl. sol. in boiling  $\text{K}_2\text{CO}_3 + \text{Aq}$ , and  $\text{KOH} +$   
Aq; see below.

Insol. in cold  $\text{KOH} + \text{Aq}$ ; extremely slowly  
sol. in boiling  $\text{KOH} + \text{Aq}$ . (Fuchs.)

Sol. in HF with formation of  $\text{SiF}_4$  and  $\text{H}_2\text{O}$ .

Insol. in sugar + Aq, contrary to assertion  
of Verdeil and Rissler. (Petzholdt, J. pr.  
60. 368.)

(b) *Amorphous*. Min. Opal, etc.

Insol. in  $\text{H}_2\text{O}$ , and acids except HF.

100 pts.  $\text{H}_2\text{O}$  containing  $\text{CO}_2$  dissolve  
0.078 pt. amorphous  $\text{SiO}_2$  (Maschke); 0.0136  
pt. (Struckmann).

100 pts. cold  $\text{HCl} + \text{Aq}$  of 1.088 sp. gr. dis-  
solve 0.017 pt.  $\text{SiO}_2$ . (Struckmann.) 100  
pts.  $\text{HCl} + \text{Aq}$  of 1.115 sp. gr. dissolve in the  
cold 0.009 pt.  $\text{SiO}_2$ , and 0.018 pt. on boiling.  
100 pts.  $\text{NH}_4\text{OH} + \text{Aq}$  (containing 10%  $\text{NH}_3$ )  
dissolve 0.017 pt. quartz and 0.38 pt. ignited  
 $\text{SiO}_2$ . (Pribram, Z. anal. 6. 119.)

Sol. in boiling  $\text{K}_2\text{CO}_3$  or  $\text{Na}_2\text{CO}_3 + \text{Aq}$ ,  
separating out on cooling as a gelatinous  
mass. (Pfaff, Schw. J. 29. 383.) The differ-  
ent forms of  $\text{SiO}_2$  have different degrees of  
solubility in  $\text{K}_2\text{CO}_3 + \text{Aq}$ . Unignited amor-  
phous  $\text{SiO}_2$  from  $\text{SiF}_4$  dissolves most readily,  
then come opal, ignited amorphous  $\text{SiO}_2$ ,  
fused  $\text{SiO}_2$ , and tridymite; quartz powder is  
the most difficultly soluble. (Rose.) A  
similar behaviour is shown to  $\text{KOH} + \text{Aq}$ .

Opal is much more sol. in  $\text{KOH} + \text{Aq}$  than  
quartz, and hyalite is the least sol. of the  
varieties of opal. (Fuchs.)

Opal is easily sol. in  $\text{KOH} + \text{Aq}$ , even after  
ignition. (Schaffgotsch, Pogg. 66. 147.)

Rammelsberg (Pogg. 112. 177) made the  
following experiments on the solubility of  
 $\text{SiO}_2$  in  $\text{KOH} + \text{Aq}$ . The  $\text{KOH} + \text{Aq}$  used con-  
tained 1 pt.  $\text{KOH}$  to 3 pts.  $\text{H}_2\text{O}$ . 1 pt. of  
the powdered mineral was boiled half an hour  
in a silver dish with such an amount of the  
 $\text{KOH} + \text{Aq}$  that 20 pts.  $\text{KOH}$  were present.

7.75% of milky white quartz was dissolved  
by repeating the above process three times.

12.8–15% of gray hornstone was dissolved  
by twice boiling; 2.43% of moderately finely  
powdered agate of 2.661 sp. gr. was dissolved  
by once boiling; 9.7% of unignited hyalite  
remained undissolved after thrice boiling.

21% of ignited hyalite remained undissolved after thrice boiling; 7.21% of semi-opal of 2.101 sp. gr. remained undissolved after thrice boiling; 18.5-19.2% of impure semi-opal of 2.101 sp. gr. remained undissolved after thrice boiling; 79.9% of chalcedony of 2.624 sp. gr. remained undissolved after thrice boiling; 6.12% of chalcedony of 2.567 sp. gr. remained undissolved after fourth boiling; 14.4% chrysoprase of 2.623 sp. gr. remained undissolved after once boiling; 49.41% of chrysoprase of 2.635 sp. gr. remained undissolved after thrice boiling; 6.62% of flint of 2.606 sp. gr. remained undissolved after twice boiling; 38.1% of fire-opal of 2.625 sp. gr. remained undissolved after fourth boiling; 26.6% of fire-opal of 2.625 sp. gr. remained undissolved after fifth boiling.

#### Silundum, $\text{Si}_2\text{C}_y$ .

Not attacked by hot Cl or conc. acids.  
 (Amberg, Z. Elektrochem. 1909, 15. 725.)

#### Silver, Ag.

Not attacked by  $\text{H}_2\text{O}$ . Absolutely insol. in  
 HCl or  $\text{HC}_2\text{H}_3\text{O}_2 + \text{Aq}$ . (Lea, *Sill. Am. J.*  
 144. 444.) Easily sol. in  $\text{HNO}_3 + \text{Aq}$  on warm-  
 ing, if not too conc. Only a minute trace is  
 dissolved in an hour by cold dil.  $\text{HNO}_3 + \text{Aq}$  (1  
 pt.  $\text{HNO}_3 + \text{Aq}$  of sp. gr. 1.40 : 10 pts.  $\text{H}_2\text{O}$ ).  
 (Lea.) Sol. in hot conc.  $\text{H}_2\text{SO}_4$  with evolution  
 of  $\text{SO}_2$ . Sl. sol. in dil.  $\text{H}_2\text{SO}_4 + \text{Aq}$  (1 : 4), but  
 with more dil.  $\text{H}_2\text{SO}_4 + \text{Aq}$  the different forms  
 of Ag behave differently. (Lea.)

Sol. in  $\text{HI} + \text{Aq}$  at ordinary temperature.

Sol. in KI+Aq with access of air. Sol. in hot KCN+Aq. (Christomanos, Z. anal. 7. 301.)

Sol. in chromic, iodic, chloric and bromic acids. Dil.  $\text{H}_2\text{SO}_4$  alone is incapable of dissolving finely divided Ag, and the seeming solvent action is due to the oxygen of the air, oxygen dissolved in the acid, or derived from some external source. (Hendrixson, J. Am. Chem. Soc. 1903, 25. 637.)

Boiling  $\text{H}_2\text{SO}_4$  dissolves pure Ag only when concentration equals 60° B. More dil. acid dissolves only the impure metal. (Pannani, Gazz. ch. it. 1909, 39. (2) 234.)

Slowly decomp. into AgCl by alkali chlorides+Aq; also by  $\text{CuCl}_2$ , etc.+Aq.

Somewhat sol. in  $\text{NH}_4\text{OH}$ +Aq in presence of O. (Lea, Sill. Am. J. 144. 444.)

Sol. in  $\text{KMnO}_4$ +dil.  $\text{H}_2\text{SO}_4$ +Aq. (Friedheim, B. 20. 2554.)

Sol. in  $\text{Fe}_2(\text{SO}_4)_3$ +Aq, especially on heating, but completely insol. in  $\text{FeSO}_4$ +Aq. (Vogel.)

Insol. in liquid  $\text{NH}_3$ . (Gore, Am. Ch. J. 1898, 20. 829.)

**Allotropic forms**—(a). Very sol. in  $\text{H}_2\text{O}$ . Solution is pptd. by saline solutions or almost any neutral substance. Alkali sulphates, nitrates, and citrates ppt. it in a sol. form, while  $\text{MgSO}_4$ ,  $\text{CuSO}_4$ ,  $\text{FeSO}_4$ ,  $\text{NiSO}_4$ ,  $\text{K}_2\text{Cr}_2\text{O}_7$ ,  $\text{K}_4\text{Fe}(\text{CN})_6$ ,  $\text{Ba}(\text{NO}_3)_2$ , and even  $\text{AgNO}_3$ +Aq ppt. it in an insol. form, which, however, may be made sol. again by treatment with many substances, as  $\text{Na}_2\text{B}_4\text{O}_7$ ,  $\text{K}_2\text{SO}_4$ , or  $\text{Na}_2\text{SO}_4$ +Aq.  $\text{NaNO}_3$ +Aq ppts. the Ag from its solution in a perfectly insol. form.

(b). The ppt. from aqueous solution by salts is sol. in  $\text{NH}_4\text{OH}$ +Aq. (Lea, Sill. Am. J. 157. 476.)

Many other allotropic forms exist. (Lea.)

Insol. in hot or cold  $\text{H}_2\text{O}$  or dil. acids; sol. in conc. mineral acids. Sol. in  $\text{NH}_4\text{OH}$ +Aq. (Curtius, B. 23. 3023.)

If flocculent or pulverulent, it is a sol. therein above 33°, but if granular above 50°, and then very slightly. (Stas, ch. (5) 3. 289.) Ag can be detected in 10,000,000 pts.  $\text{H}_2\text{O}$ . (Stas.)

Calculated from the electrical conductivity of  $\text{AgBr}$ +Aq,  $\text{AgBr}$  is sol. in 1,971.6  $\text{H}_2\text{O}$  at 20.2°, and 775,400 pts. at 38°. (Pannani, Z. phys. Ch. 12. 133.)

The following data are for a more or less impure Ag<sub>2</sub>Cl.

Boiling conc. HCl + Aq, NaCl + Aq, or NH<sub>4</sub>OH + Aq dissolve out AgCl, and leave Ag. (Scheele, Wetzlar. Dulk, Wöhler.)

According to Berthollet, wholly sol. in NH<sub>4</sub>OH + Aq. Sol. for the most part in NH<sub>4</sub>OH + Aq, and the residue is sol. in HNO<sub>3</sub> + Aq (= Ag + AgCl). (v. Bibra, B. 7. 741.)

Silver chloride, AgCl.

Nearly insol. in H<sub>2</sub>O.

When AgCl is left in contact for some hours with pure H<sub>2</sub>O at 20-22°, and especially at 75°, traces go into solution; more Cl is dissolved than Ag. When 1 pt. Ag is pptd. as AgCl in presence of 1 million pts. H<sub>2</sub>O a slight bluish milkiness is observed; but in order to have a distinct ppt. 4 pts. Ag should be present.

Dil. HNO<sub>3</sub> + Aq does not increase the solubility of AgCl, but AgCl is not absolutely insol. in stronger HNO<sub>3</sub> + Aq. (Mulder.)

1 pt. AgNO<sub>3</sub>, when mixed with HCl + Aq in presence of 120,000 (Pfaff), 240,000 (Harting), pts. H<sub>2</sub>O, causes an opalescence.

1 pt. Ag gives a slight turbidity with HCl + Aq in presence of 200,000 pts. H<sub>2</sub>O, a scarcely opalescent cloudiness with 400,000 pts. H<sub>2</sub>O, and the same after the lapse of 15 minutes in presence of 800,000 pts. H<sub>2</sub>O. (Lassaigne.)

1 pt. Ag can be detected as AgCl in 1 million parts H<sub>2</sub>O at ordinary temp., but not in 2 million parts. In NaNO<sub>3</sub> + Aq containing 0.79 pt. NaNO<sub>3</sub> in 200,000 pts. H<sub>2</sub>O, 1 pt. Ag can be detected as AgCl. This dissolves at 75°, and is visible again on cooling.

If the same liquid contains 1574 pts. NaNO<sub>3</sub>, the AgCl remains in solution after cooling.

In 100 ccm.  $H_2O$  containing 0.787 g.  $NaNO_3$ , 13 drops of  $NaCl$  and silver solution, each drop of which contains 0.05 mg. Ag, cause a precipitate at 5°, 20 drops at 15-17°, 60 drops at 45-55°.

$AgCl$  is somewhat less sol. in  $HNO_3$  + Aq than in  $NaNO_3$  + Aq when the amount of  $H_2O$  remains the same.

Therefore, if  $HCl$  is used instead of  $NaCl$ , about  $\frac{1}{7}$  less  $AgCl$  remains in solution.

In 100,000 pts. of  $H_2O$ , which contain  $HNO_3$ , and an amount of  $HCl$  corresponding to the amount of Ag salt, 1,596 pts.  $AgCl$  dissolve at 25°. The solution is precipitated by either  $AgNO_3$  or  $HCl$ . (Mulder, Silber Probir-methode, Leipzig, 1859. 62.)

(For further older data, see Storer's Dictionary.)

White flaky  $AgCl$  is appreciably sol. in hot  $H_2O$ , 1000 ccm. boiling  $H_2O$  dissolving about 2 mg.  $AgCl$ . Far less sol. in  $H_2O$  containing  $AgNO_3$ , being practically insol. in  $H_2O$  containing 0.1 g.  $AgNO_3$  in a litre. Solubility is also diminished one-half by addition of  $HCl$ . (Cooke, Sill. Am. J. (3) 21. 220.)

Solubility in  $H_2O$  rapidly diminishes as the temp. falls. (Cooke, *l. c.*)

Not completely insol. in  $H_2O$ . According to Stas (C. R. 73. 998) there are four modifications: (1) gelatinous; (2) cheesy-flocculent; (3) pulverulent; (4) granular, crystalline, or fused. (4) is almost absolutely insol. in  $H_2O$  at the ordinary temp., but the solubility increases with the temp., and is considerable at 100°; (2), which is formed by the precipitation of a cold dilute Ag solution, has the greatest solubility in pure  $H_2O$ , and it changes its solubility by standing, or if made pulverulent by shaking with  $H_2O$ ; (3) is also sol. in  $H_2O$ ; the solution of (2) or (3) in pure  $H_2O$ , or  $H_2O$  acidified with  $HNO_3$ , is precipitated by  $AgNO_3$ , or  $NaCl$  + Aq.

In order to ppt. 1 pt.  $AgCl$  in above solution 3 pts. of  $Cl$  as chloride or Ag as nitrate are necessary; the pptn. is then complete.

Solubility of granular variety in boiling  $H_2O$  is proportionately large, and pptn. is brought about by 3 pts.  $Cl$  or Ag as above, but the pptn. in this case is not complete.

The salts formed simultaneously with the  $AgCl$  have no influence on the solubility of the  $AgCl$ . Presence of  $HNO_3$  does not increase the solubility of (2), but has that effect on (3) in proportion to the amt. of  $HNO_3$  present. (Stas, C. R. 73. 998.)

Further determination by Stas are as follows:—

Between 0° and 30° granular  $AgCl$  is insol. in pure  $H_2O$ , or  $H_2O$  acidulated with  $HNO_3$ .

Between 0° and 30° the flocculent and pulverulent forms of  $AgCl$  dissolve without alteration in pure  $H_2O$ , in acidulated  $H_2O$ , in alkali acetates + Aq, and in  $Hg(C_2H_3O_2)_2$  + Aq containing an alkali acetate. Their degree of solubility is a function of the state of the chloride, of the temp., and of the nature

and quantity of the solvent within limits of temp. (0°-30°). These solv. they contain either Ag in the state of salt, or  $Cl$  as chloride or  $HCl$  in an amount three times that which they can dissolve.  $AgCl$ , exercise no solvent action on any modifications of  $AgCl$ . And reciprocal  $AgCl$  + Aq is pptd. instantly by a dec. solution of  $AgNO_3$ , or  $MCl$  (or  $HCl$ )  $AgCl$  is wholly pptd. when the quantity of the Ag or  $Cl$  thus added is equal to three times the quantity of the Ag or  $Cl$  dissolved as  $AgCl$ .

Between 50° and 100°, however, dec. solutions of Ag or chlorides, which give instant ppts. in solutions sat. with any modifications of  $AgCl$ , do not eliminate the dissolved  $AgCl$ . At 100°, they dissolve 60% of the amt. dissolved. (Stas, A. 3. 323.)

Calculated from electrical conductivity,  $AgCl$  + Aq,  $AgCl$  is sol. in 715,800 pts. at 13.8°, and 384,100 pts. at 26.5°. (Noyes, Z. phys. Ch. 12. 132.)

Calculated in the same way, 1. dissolves 0.76 mg. at 2°; 0.97 mg. at 18°; 2.24 mg. at 26°; 3.03 mg. at 42°. (Kohlrausch and phys. Ch. 12. 242.)

(Lowry, Roy, Soc. Proc. **1914**, **91**, A. 62.)

Sl. sol. in conc. HBr + Aq. (Löwig.)

Insol. in HNO<sub>3</sub> + Aq. (Wackenroder.)

Entirely unacted upon by HNO<sub>3</sub> of 1.43 sp. gr. (Wurtz, Am. J. Sci. (2) **25**, 382.)

Solubility in dil. HNO<sub>3</sub> + Aq is the same as solubility in H<sub>2</sub>O, i. e.  $\frac{1}{2,000,000}$  pt. of Ag cannot be detected in H<sub>2</sub>O with or without HNO<sub>3</sub>, but  $\frac{1}{1,000,000}$  pt. can be detected in both cases. (Mulder.)

1 pt. Ag in the form of AgCl dissolves at 25° in 83,000 pts. H<sub>2</sub>O containing free HNO<sub>3</sub>, and 0.33 pt. of HCl. (Mulder.)

100,000 pts. conc. HNO<sub>3</sub> + Aq dissolve about 2 pts. AgCl, and solubility is not sensibly affected by lower nitrogen oxides. (Thorpe, Chem. Soc. (2) **10**, 453.)

$\text{AgCl}$  is not more sol. in dil.  $\text{H}_2\text{SO}_4 + \text{Aq}$  than in dil.  $\text{HNO}_3 + \text{Aq}$ .

Sat.  $\text{CuCl}_2 + \text{Aq}$  at  $0^\circ$  dissolves 2.835 g.  $\text{AgCl}$  per l; at  $100^\circ$ , 8.147 g. Solubility in sat.  $\text{MgCl}_2 + \text{Aq}$  is still greater. (Hahn, *Eng. Min. J.* 65. 434.)

More sol. in  $\text{HgCl}_2 + \text{Aq}$  than in  $\text{H}_2\text{O}$ . (Finsz, Gazz. ch. it. 1902, 32. (2) 324.)

At  $15^\circ$ , 100 g.  $\text{NaCl}$  in 280 ccm.  $\text{H}_2\text{O}$  dissolve 485 mg.  $\text{AgCl}$ ; 100 g.  $\text{KCl}$  in 300 ccm.  $\text{H}_2\text{O}$  dissolve 334 mg.; 100 g.  $\text{NH}_4\text{Cl}$  in 280 ccm.  $\text{H}_2\text{O}$  dissolve 1051 mg.

The solubility decreases with dilution rapidly at first until about an equal vol. of  $\text{H}_2\text{O}$  has been added, and then much more slowly to a minimum quantity, when the dilution is 1 : 10 for  $\text{NaCl}$  and  $\text{KCl}$ , and 1 : 20 for  $\text{NH}_4\text{Cl}$ .

100 g.  $\text{NaCl}$  in 280 ccm.  $\text{H}_2\text{O}$  dissolve 2170 mg.  $\text{AgCl}$  at  $109^\circ$ ; 100 g.  $\text{NH}_4\text{Cl}$  in 280 ccm.  $\text{H}_2\text{O}$  dissolve 4000 mg.  $\text{AgCl}$  at  $110^\circ$ ; 100 g.  $\text{NaCl}$  in 620 ccm.  $\text{H}_2\text{O}$  (14% solution) dissolve 15 mg.  $\text{AgCl}$  at  $15^\circ$ , and 774 mg. at  $104^\circ$ . at 25°, 100,000 pts.  $\text{H}_2\text{O}$  containing a little  $\text{HNO}_3$  and 0.787 g.  $\text{NaNO}_3$  dissolve 2.128

AgCl. By adding 2 g. more  $\text{NaNO}_3$  to the solution, 2.5269 mg. ( $\frac{1}{10}$  more) AgCl are dissolved. (Mulder.)

Solubility in  $\text{H}_2\text{O}$  is not appreciably increased by  $\frac{1}{10}$  N to N- $\text{KNO}_3$  or  $\text{NH}_4\text{NO}_3$  + (van Rossum, C. C. 1912, II. 1807.)

In presence of  $\text{NaNO}_3$  and excess of  $\text{HCl}$ ,  $\text{H}_2\text{O}$  dissolves 0.03 mg. AgCl. (Richards, Wells.)

$\text{Hg(NO}_3)_2$  + Aq dissolves considerable quantities of AgCl, but the other nitrates do not. (Mulder.)

Much more sol. in hot than in cold ( $\text{NO}_3$ )<sub>2</sub> + Aq, and much more sol. therein than in  $\text{NH}_4\text{NO}_3$  + Aq.  $\text{NaCl}$  ppts. AgCl in this solution; much less sol. therein in

presence of  $\text{NaC}_2\text{H}_3\text{O}_2$  or  $\text{NH}_4\text{OH}$  + Aq. AgCl is pptd. from above solution by  $\text{NaC}_2\text{H}_3\text{O}_2$  + Aq. (Mulder.)

Sol. in  $\text{Hg(NO}_3)_2$  + Aq (Wackenroder, A. 41. 317); in considerable amount (Liebig, A. 81. 128); and is precipitated by  $\text{HCl}$ ,  $\text{NH}_4\text{Cl}$ ,  $\text{NaCl}$ ,  $\text{KC}_2\text{H}_3\text{O}_2$  (Debray, C. R. 70. 849); incompletely precipitated by  $\text{AgNO}_3$  and not by  $\text{HNO}_3$  (Wackenroder).

$\text{HNO}_3$  was present in all cases, and it was found that there was no difference in solubility of AgCl with concentrations between 0.1N and 2N  $\text{HNO}_3$ . (Morse, Z. phys. Ch. 1902, 45. 708.)

(Barfoed, J. pr. 101. 368.)

Insol. in K<sub>2</sub>CO<sub>3</sub> + Aq (Rose); alkali carbonates + Aq. (Fremy.)

A colloidal metastannic acid sol. in H<sub>2</sub>O can be obtained. (Lepéz and Storch.)

According to Weber (Pogg. 122. 358), stannic and metastannic acids are only different hydrates of same oxide, and it is not a case of allotropic modification.

This solution is coagulated by HNO<sub>3</sub> + Aq only when in great excess; easily by dil. H<sub>2</sub>SO<sub>4</sub> + Aq, but not by conc. HCl + Aq. NH<sub>4</sub>OH + Aq in large excess causes coagulation; also NH<sub>4</sub>Cl, NaOH, NaCl, Na<sub>2</sub>SO<sub>4</sub>, etc. (Schneider, Z. anorg. 5. 83.)

**Sulphur, S.**

The various modifications of sulphur have been classified in many different ways, and there is a difference of opinion as to whether certain forms are true allotropic modifications or not.

The data, as far as concerns the solubility, may be arranged as follows:—

A. Sol. in  $\text{CS}_2$ . 1. Rhombic, octahedral, or alpha sulphur, ordinary sulphur. Easily sol. in  $\text{CS}_2$ , etc. See below for solubility in various solvents.

2. Prismatic, monoclinic, or beta sulphur. Sol. in  $\text{CS}_2$ , but is converted into A, 1. Prismatic sulphur obtained by melting brimstone is not wholly sol. in  $\text{CS}_2$  on account of admixture of gamma sulphur.

Monoclinic modification is more sol. than rhombic in  $\text{CHCl}_3$ , ether and benzene. (Meyer C. C. 1903, II. 481.)

3. Soft sulphur, milk of sulphur.

4. Amorphous sol. sulphur is also a separate modification, according to Berthelot.

B. Soft sulphur, obtained by strongly heating and quickly cooling, is sol. in  $\text{CS}_2$ , but becomes insol. therein by repeatedly dissolving and evaporating. More easily sol. in  $\text{CS}_2$  than A, 1.

C. Insol. in  $\text{CS}_2$ . 1. By action of strong light on S in  $\text{CS}_2$ .

2. By heating to b.-pt., cooling suddenly, and allowing to stand until hard. Has been called gamma sulphur, but is a mixture of  $\frac{2}{3}$  A, 4 and  $\frac{1}{3}$  insol. S.

3. Insol. S in flowers of sulphur. Converted into A, 1 by standing 3 days with alcohol.

According to Berthelot (A. ch. (3) 49. 430) there are only two varieties of S. I. "Octahedral," II. "Amorphous."

I. Octahedral. Sol. in  $\text{CS}_2$ . Scarcely acted upon by  $\text{KHSO}_4 + \text{Aq}$ . Converted by oxidising agents into II.

II. Amorphous. Insol. in neutral solvents viz.  $\text{H}_2\text{O}$ , alcohol, ether,  $\text{CS}_2$ , etc.

Sol. with tolerable rapidity in  $\text{KHSO}_4 + \text{Aq}$ . By long action of  $\text{Na}_2\text{S} + \text{Aq}$ , a portion is dissolved, and the remainder converted into I. Less easily oxidised by  $\text{HNO}_3 + \text{Aq}$  than I.

Some varieties of this modification are sol. to a certain extent in alcohol and ether, and by boiling the rest of the sulphur is converted into I; also by long-continued contact with cold alcohol. Berthelot holds that the modification is changed before dissolving. Solutions of the alkalis, alkali salts, and alkali sulphides change insol. into sol. sulphur (Berthelot.)

Elastic sulphur obtained by pouring molten sulphur at a temp. of over  $260^\circ$  into  $\text{H}_2\text{O}$  contains 35% or more of a modification of S which is insol. in  $\text{CS}_2$ , hot or cold, but sol. in absolute alcohol; this modification can be converted back into ord. sulphur by heating to  $100^\circ$ . (Pelouse and Fremy.) (See C. 2.)

This modification can be obtained also by action of  $\text{HCl}$  on thiosulphates. (Fordes and Gélis.)

The soft pasty sulphur obtained by decomposition of  $\text{H}_2\text{S}$  by  $\text{SO}_2$  forms an almost clear emulsion (pseudo-solution) with  $\text{H}_2\text{O}$ , from which it is pptd. by various salts and substances which have no chemical affinity for it. 23 pts. S combine in this way with 100 pts.  $\text{H}_2\text{O}$ . When pptd. by saline solutions, some of the S remains in solution. When solution is exposed to the light, S gradually separates out; also on boiling the same takes place. The above pseudo-solution is pptd. by mineral acids, and the pptd. S may still be dissolved in fresh water, if not left in contact for some time with the acid. Also pptd. by K salts, with loss of power of forming pseudo-solutions. Pptd. by  $\text{NH}_4$  and Na salts without losing that power.

**Alkali** hydrates, carbonates, or sulphides convert it into insol. S.

The solution may be mixed with alcohol without change. Decomp. by long shaking with naphtha or oil of turpentine. The pseudo-solution combines with  $\text{CS}_2$ , forming an emulsion which subsequently decomposes. The S itself is only partially sol. in  $\text{CS}_2$ . (Selmi, J. pr. 57. 49.)

By treatment of amorphous "insoluble" S with  $\text{CS}_2$  or  $\text{CCl}_4$ , a small part goes into solution, the amount being dependent on the time of contact with the temp., and nature of the solvent, but independent of the amount of the solvent. It is assumed that this is due to a partial change of the "insoluble" into soluble S. (Wigand, Z. phys. Ch. 1910, 75. 235.)

"Delta" sulphur. Partly sol. in  $\text{H}_2\text{O}$ . (Debus, Chem. Soc. 53. 18.)

A colloidal form wholly sol. in  $\text{H}_2\text{O}$  exists, which, however, decomposes very easily. (Engel, C. R. 112. 866.)

**Black sulphur.** Insol. in alcohol, ether,  $\text{CS}_2$ , fatty oils even at  $200^\circ$ , cold alkali hydroxides + Aq,  $\text{H}_2\text{SO}_4$ ,  $\text{HNO}_3$ , or aqua regia. (Knapp, J. pr. (2) 43. 305.)

**Green modification.** Five times more sol. than ordinary sublimed sulphur in a mixture of salicylaldehyde and benzene. (Orloff, C. C. 1902, 1. 1264.)

The following data relate to octahedral or ordinary sulphur (A. 1):—

Sol. in warm liquid  $\text{H}_2\text{S}$  (Niemann); warm  $\text{P}_2\text{S}_5$ ,  $\text{SBr}_2$ ,  $\text{SCl}_2$ ,  $\text{Br}_2$ ,  $\text{NCl}_3$ ,  $\text{BaS} + \text{Aq}$  (Dumas); in alcoholic solution of  $\text{K}_2\text{S}_2$ , but is reprecipitated by addition of  $\text{H}_2\text{O}$  to sat. solution.

Sol. in liquid  $\text{SO}_2$ .

Sol. in aqueous solution of alkali sulphates, especially when hot. Sl. sol. in boiling conc.  $\text{HSCN} + \text{Aq}$ , from which it mostly separates on cooling.

$\text{Na}_2\text{CO}_3 + \text{Aq}$  (5.6%  $\text{Na}_2\text{CO}_3$ ) dissolves no S at  $20^\circ$ ; 0.06775% at  $100^\circ$ . (Pohl, Dingl. 197. 508.)

The solubility of S in  $\text{Na}_2\text{S} + \text{Aq}$  between  $0^\circ$  and  $50^\circ$  diminishes slightly with increase in temp., but increases with dilution of the solution, having its largest value in a N/16 solution of  $\text{Na}_2\text{S} + \text{Aq}$  when the relation of  $\text{Na}_2\text{S}$  to dissolved S equals about 1:4. (Küster, Z. anorg. 1905, 43. 56.)

Sol. in  $\text{AlBr}_3$ . (Isbekow, Z. anorg. 1913, 84. 27.)

Insol. in liquid  $\text{CO}_2$ . (Büchner, Z. phys. Ch. 1906, 54. 674.)

Sol. in liquid  $\text{NH}_3$ . 1 gr. S is sol. in 3-4 cc. liquid  $\text{NH}_3$ . (Hugot, A. ch. 1900, (7) 21. 32.)

The solubility of S in liquid  $\text{NH}_3$  is constant from  $-23^\circ$  to  $-84^\circ$  and equals 39%. (Ruff, Z. anorg. Ch. 1910, 23. 1830.)

A mixture of S and toluene separates into two layers, containing 33 and 92.5% S respectively. (Haywood, J. phys. Ch. 1897, 1. 232.)

CS<sub>2</sub> dissolves 0.35 pt. ordinary sulphur; some varieties of S, however, are not entirely sol. in CS<sub>2</sub>, thus—

+  $5\text{H}_2\text{O}$ . Is ammonium chromosulphate,  
which see.

+  $24\text{H}_2\text{O}$ . **Chrome Alum.**

**Violet modification.** Efflorescent. Sol. in  
cold  $\text{H}_2\text{O}$ , but solution is decomp. on heating  
with formation of green modification. The  
dil. solution of green modification is grad-  
ually converted into violet modification by  
standing. Alcohol ppts. it from aqueous  
solution. (Schrötter, Pogg. 53. 526.)

100 cc.  $\text{H}_2\text{O}$  dissolve 10.78 g. anhydrous, or  
21.21 g. hydrated salt at  $25^\circ$ . Melts in crystal  
 $\text{H}_2\text{O}$  at  $45^\circ$ . (Locke, Am. Ch. J. 1901. 28. 174.)

**Solubility in  $\text{H}_2\text{O}$ .**

Saturation is very slowly reached owing to  
transition between violet and green modifi-  
cations. If time of saturation is taken at  
 $2\frac{1}{2}$  hours, 100 g. of the solution contain at:

$0^\circ$   $30^\circ$   $40^\circ$

3.77 10.6 15.5 g.  $(\text{NH}_4)_2\text{Cr}_2(\text{SO}_4)_4$ .

This is assumed to be the solubility of the  
violet modification.

In 300 hours, 15.96 g. salt are dissolved  
at  $30^\circ$ , and 24.64 g. in 250 hours at  $40^\circ$ .  
(Koppel, B. 1906, 39. 3741.)

Calc. from electrical conductivity measure-  
ments, a solution containing 3.8 g. of the  
sulphate in 100 g. contains 48% of the green  
compound at  $40^\circ$  and 61% at  $55^\circ$ . With  
solutions of 6-7 times the above concentra-  
tion equilibrium is reached at  $40^\circ$  with 30-  
40% green alum. (Koppel.)

Sat. solution at  $15^\circ$  has sp. gr. = 1.070.

cohol. When in aqueous solution, it gradually  
changes to violet modification.

Not attacked by cold  $HCl$  or  $HNO_3$ +Aq after several hours, and only in traces after several days. On boiling, traces of  $BaSO_4$  dissolve, and the liquid after cooling can be precipitated by  $BaCl_2$  or  $H_2SO_4$ +Aq, but not by  $H_2O$  alone. (Rose, Pogg. 95. 108.)

By washing  $BaSO_4$  long enough with  $H_2O$  containing  $HCl$  or  $HNO_3$  [ $HC_2H_3O_2$  (Siegle)], the filtrate can be precipitated by  $H_2SO_4$  or  $BaCl_2$ . (Piria, J. B. 1856. 334.)

At  $15^\circ$  and after 5 minutes shaking, the highest degree of supersaturation which can be obtained with pure sol. calcium sulphate = 9.47 g. of the anhydrous salt or 11.976 g.  $\text{CaSO}_4 + 2\text{H}_2\text{O}$  in 1 l. of  $\text{H}_2\text{O}$ . (Cavazzi, C. C. 1905, I, 1694.)

Min. *Uranocalcite*.

Min. *Medjidite*. Easily sol. in dil.  $\text{HCl} + \text{aq}$ .

**Cerous sulphate,  $\text{Ce}_2(\text{SO}_4)_3$ .**

Anhydrous cerous sulphate is much more sol. in  $\text{H}_2\text{O}$  than the hydrated salt.

Easily sol. in cold  $\text{H}_2\text{O}$  if added thereto in small amounts. If large amount of  $\text{Ce}_2(\text{SO}_4)_3$  is treated with a little  $\text{H}_2\text{O}$  it hardens with evolution of heat, and becomes very difficultly soluble. 100 pts.  $\text{H}_2\text{O}$  dissolve 161 pts.  $\text{Ce}_2(\text{SO}_4)_3$  at  $0^\circ$  and 17.86 pts. at  $19^\circ$ .

$\text{Ce}_2(\text{SO}_4)_3 + \text{Aq}$  sat. in cold deposits  $\text{Ce}_2(\text{SO}_4)_3$  at  $75^\circ$ , and only 2.25 pts. remain in solution at  $100^\circ$ . (Jolin, Bull. Soc. (2) 21. 336.)

100 pts.  $\text{H}_2\text{O}$  dissolve 8.31 pts.  $\text{Ce}_2(\text{SO}_4)_3$  at  $20^\circ$ ; 8.08 pts. at  $45^\circ$ ; 4.95 pts. at  $60^\circ$ ; 0.504 pt. at  $100^\circ$ . (Bühlig, J. pr. (2) 12. 240.)

60 pts. anhydrous salt dissolve quickly at  $-3^\circ$  in 100 pts.  $\text{H}_2\text{O}$ .

At  $15^\circ$  the solution solidifies, and the mother liquor contains only 27.88%  $\text{Ce}_2(\text{SO}_4)_3$ . At  $15^\circ$  the maximum attainable strength is 31.62%  $\text{Ce}_2(\text{SO}_4)_3$ . (Brauner, Chem. Soc. 53. 357.)

100 pts.  $\text{H}_2\text{O}$  dissolve 10.747 pts.  $\text{Ce}_2(\text{SO}_4)_3$  at  $16^\circ$ ; 9.648 pts. at  $19^\circ$ ; 6.949 pts. at  $33^\circ$ .

The solubility of  $\text{Ce}_2(\text{SO}_4)_3$  in  $\text{H}_2\text{O}$  is diminished by the addition of  $(\text{NH}_4)_2\text{SO}_4$ ,  $\text{K}_2\text{SO}_4$  or  $\text{Na}_2\text{SO}_4$ . (Barre, C. R. 1910, 151. 872.)

Sp. gr. of  $\text{Ce}_2(\text{SO}_4)_3 + \text{Aq}$  was found to be constant whether  $\text{Ce}_2(\text{SO}_4)_3$  or  $\text{Ce}_2(\text{SO}_4)_3 + 8\text{H}_2\text{O}$  was used. The following results were obtained at  $15^\circ$ .

According to Traube (A. **71**, 92) and Siewert (A. **126**, 94), Schrötter's salt is an acid sulphate,

When the  $\text{H}_2\text{O}$  solution is heated to  $65-70^\circ$  it begins to be converted into the green modification. This conversion is also brought about by cold  $\text{HNO}_3$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{PCl}_5$ . (Étard, C. R. **84**, 1090.)

More easily sol. in sat.  $\text{K}_2\text{SO}_4 + \text{Aq}$  than in  $\text{Na}_2\text{SO}_4$  or  $\text{MgSO}_4 + \text{Aq}$ , forming a double sulphate, which separates out. (Karsten.) $\text{K}_2\text{SO}_4$  and  $\text{CuSO}_4$  mutually displace each other in saturated solutions. (Rüdorff, Pogg. 148. 555.)When  $\text{K}_2\text{SO}_4$  and  $\text{CuSO}_4$  both in excess, are dissolved in  $\text{H}_2\text{O}$ , a maximum of solubility of 15.61 pts. of the two salts in 100 pts.  $\text{H}_2\text{O}$  at  $25^\circ$  is reached in 30 minutes, after which the solubility decreases. This result is obtained either by treating excess of the two salts with  $\text{H}_2\text{O}$  at  $25^\circ$ , or cooling solutions of the two salts sat. at higher temp. to  $25^\circ$ . The salts are in the proportion of 5.2 pts.  $\text{K}_2\text{SO}_4$  to 10.4 pts.  $\text{CuSO}_4$ . If present in the same proportion as in their saturated solutions, 5.41 pts.  $\text{K}_2\text{SO}_4$  to 10.13 pts.  $\text{CuSO}_4$  would be required.

If sat. solution of one salt is added to sat. solution of the other,  $K_2Cu(SO_4)_2 + 6H_2O$  separates, as it is less sol. than either simple salt, until a state of equilibrium is reached, after which there is no separation, contrary to Rüdorff (see above). (Trevor, Z. phys. Chem. 7. 486.)

The solubility of  $\text{NO}$  in  $\text{FeSO}_4 + \text{Aq}$  is diminished by the presence of  $\text{H}_2\text{SO}_4$ ,  $\text{HCl}$ , phosphoric acid and by the presence of certain salts. (Manchot, A. 1910, 372, 157.)

$+ 6\text{H}_2\text{O}$ , and  $+ 7\text{H}_2\text{O}$ . The latter exists in two modifications; (a) hexagonal, and (b) the ordinary or rhombic salt.

$\text{MgSO}_4 + \text{Aq}$ , which on cooling or keeping in closed vessels has deposited  $\text{MgSO}_4 + 6\text{H}_2\text{O}$ , always contains for 100 pts.  $\text{H}_2\text{O}$  at:

$0^\circ$	$10^\circ$	$20^\circ$
40.75	42.23	43.87 pts. $\text{MgSO}_4$ .

If only hexagonal  $\text{MgSO}_4 + 7\text{H}_2\text{O}$  has been deposited, then the mother liquor contains for 100 pts.  $\text{H}_2\text{O}$  at:

$0^\circ$	$10^\circ$	$20^\circ$
34.67	38.71	42.84 pts. $\text{MgSO}_4$ .

Solutions prepared from rhombic  $\text{MgSO}_4 + 7\text{H}_2\text{O}$  contain for 100 pts.  $\text{H}_2\text{O}$  at:

$0^\circ$	$10^\circ$	$20^\circ$
26.0	30.9	35.6 pts. $\text{MgSO}_4$ .

(Löwel.)

These results may be given in tabular form as follows:

Temp.	A sat. aqueous solution of $\text{MgSO}_4 + 7\text{H}_2\text{O}$ (b) contains for 100 pts. $\text{H}_2\text{O}$	
	Anhydrous $\text{MgSO}_4$	$7\text{H}_2\text{O}$ (b) salt
$0^\circ$	26.0	73.31
$10^\circ$	30.9	93.75
$20^\circ$	35.6	116.54

Temp.	A sat. aqueous solution of $\text{MgSO}_4 + 7\text{H}_2\text{O}$ (a) contains for 100 pts. $\text{H}_2\text{O}$	
	Anhydrous $\text{MgSO}_4$	$7\text{H}_2\text{O}$ salt
$0^\circ$	34.67	111.74
$10^\circ$	38.71	133.67
$20^\circ$	42.84	159.61

Temp.	A sat aqueous solution of $\text{MgSO}_4 + 6\text{H}_2\text{O}$ contains for 100 pts. $\text{H}_2\text{O}$		
	Anhydrous $\text{MgSO}_4$	$6\text{H}_2\text{O}$ salt	$7\text{H}_2\text{O}$ salt
$0^\circ$	40.75	122.22	146.02
$10^\circ$	42.32	129.44	155.53
$20^\circ$	43.87	137.72	167.97

It is seen from table that at the same temp. the  $6\text{H}_2\text{O}$  salt is more sol. than the  $7\text{H}_2\text{O}$  salt, and the latter is more sol. than  $7\text{H}_2\text{O}$  salt; that the solubility of the  $7\text{H}_2\text{O}$  (b) salt increases rapidly from  $0^\circ$  to  $20^\circ$ ; that the  $6\text{H}_2\text{O}$  salt is not much more sol. at  $20^\circ$  than at  $0^\circ$ , and at  $20^\circ$  the  $7\text{H}_2\text{O}$  (b) salt is nearly as sol. as the  $6\text{H}_2\text{O}$  salt. When  $\text{MnSO}_4 + 7\text{H}_2\text{O}$  is boiled with absolute alcohol none is dissolved, but  $\text{MnSO}_4 + 3\text{H}_2\text{O}$  is formed.

When  $\text{MnSO}_4 + 7\text{H}_2\text{O}$  is dissolved in 15–50% alcohol, the liquid separates into two layers, the lower containing less (12–14%) alcohol and more (47–49%) salt; the upper containing

more (50-55%) alcohol and less (1.3-2.2%) salt. If the alcohol has the above strength (15-50%) the separation takes place at ordinary temp., but with 13-14% or 60% or more alcohol, warming is necessary to effect the separation. (Schiff, A. 118. 363.)

Up to 33°, the solubility of  $Ag_2SO_4$  in  $Na_2SO_4 + Aq$  increases with the concentration of  $Na_2SO_4$ ; above 33° the solubility of  $Ag_2SO_4$  rises to a maximum at a certain concentration of  $Na_2SO_4$  dependent on the temp. The

solubility curves for various temp. all end at concentration of 40%  $Na_2SO_4$ , that is, the mixed crystals formed at this concentration are equally sol. at all temp.

(Möller, Pogg. 117. 386.)

The solubility of  $\text{Na}_2\text{SO}_4 + 10\text{H}_2\text{O}$  increases with the temperature from  $0$  to  $34^\circ$ . At  $34^\circ$  and above, it is converted into the anhydrous salt, the solubility of which is least at  $103.17^\circ$ , which is the boiling point of the saturated solution, and increases by cooling from that temp. down to  $18-17^\circ$ . Below the latter temperature the anhydrous salt cannot exist in the presence of  $\text{H}_2\text{O}$ , but is converted into  $\text{Na}_2\text{SO}_4 + 7\text{H}_2\text{O}$ , or  $\text{Na}_2\text{SO}_4 + 10\text{H}_2\text{O}$ . The solubility of  $\text{Na}_2\text{SO}_4 + 7\text{H}_2\text{O}$  increases with the temperature from  $0-26^\circ$ , and at  $27^\circ$  it is converted into the anhydrous salt.

Thus there are two different rates of solubility for  $\text{Na}_2\text{SO}_4$  for temperatures from  $0-18^\circ$ , three different rates from  $18-26^\circ$ , two from  $26-34^\circ$ , and only one above  $34^\circ$ .

1. By heating  $\text{Na}_2\text{SO}_4 + 10\text{H}_2\text{O}$  to fusion and raising the heat until the liquid boils, placing in a closed vessel and cooling, the greater part of the anhydrous salt, which separates out on heating, redissolves on cooling, and the amount increases as the temp. falls until  $18^\circ$  is reached. Below  $18^\circ$   $\text{Na}_2\text{SO}_4 + 7\text{H}_2\text{O}$  is formed. Saturated  $\text{Na}_2\text{SO}_4 + \text{Aq}$  thus obtained contains for 100 pts.  $\text{H}_2\text{O}$  at:

18°	20°	25°	26°
53.25	52.76	51.53	51.31 pts. $\text{Na}_2\text{SO}_4$ .
30°	33°	34°	36°
50.37	49.71	49.53	49.27 pts. $\text{Na}_2\text{SO}_4$ .

2. By allowing the boiling saturated solution free from undissolved salt to cool to  $0^\circ$

with exclusion of air until crystals of  $\text{Na}_2\text{SO}_4 + 7\text{H}_2\text{O}$  are formed, then removing the greater part of the mother liquor with a warm pipette, and warming the rest of the mother liquor with the excess of crystals, the crystals dissolve in increasing quantity between  $0^\circ$  and  $26-27^\circ$ , so that at  $27^\circ$  the solution contains 56 pts.  $\text{Na}_2\text{SO}_4$  to 100 pts.  $\text{H}_2\text{O}$ . The remaining undissolved crystals of  $\text{Na}_2\text{SO}_4 + 7\text{H}_2\text{O}$  begin to melt very slowly at  $27^\circ$ , more quickly at higher temperatures, and cause the separation of anhydrous crusts, and thus the strength of the solution is gradually lowered to the normal. Saturated solutions prepared in this way contain for 100 pts.  $\text{H}_2\text{O}$  at:

$0^\circ$	$10^\circ$	$13^\circ$
19.62	30.49	34.27 pts. $\text{Na}_2\text{SO}_4$ ,
or 44.89	78.9	92.9 pts. $\text{Na}_2\text{SO}_4 + 7\text{H}_2\text{O}$ .
$15^\circ$	$16^\circ$	$17^\circ$

$18^\circ$	$19^\circ$	$20^\circ$

or 124.6	133.0	140.0 pts. $\text{Na}_2\text{SO}_4 + 7\text{H}_2\text{O}$ ,
$25^\circ$	$26^\circ$

or 188.5	202.6	pts. $\text{Na}_2\text{SO}_4 + 7\text{H}_2\text{O}$ .

3. Solutions obtained by shaking  $\text{H}_2\text{O}$  with  $\text{Na}_2\text{SO}_4 + 10\text{H}_2\text{O}$  contain for 100 pts.  $\text{H}_2\text{O}$  at:

$0^\circ$	$10^\circ$	$15^\circ$
5.02	9.00	13.20 pts. $\text{Na}_2\text{SO}_4$ ,
or 12.16	23.04	35.96 pts. $\text{Na}_2\text{SO}_4 + 10\text{H}_2\text{O}$ ,
$18^\circ$	$20^\circ$	$25^\circ$
16.80	19.40	28.00 pts. $\text{Na}_2\text{SO}_4$ ,
or 48.41	58.85	98.48 pts. $\text{Na}_2\text{SO}_4 + 10\text{H}_2\text{O}$ ,

or 323.1	412.2	pts. $\text{Na}_2\text{SO}_4 + 10\text{H}_2\text{O}$ .

At  $34^\circ$ ,  $\text{Na}_2\text{SO}_4 + 10\text{H}_2\text{O}$  begins to melt in its crystal  $\text{H}_2\text{O}$ . As long as there is a considerable quantity of unchanged crystals present, the solution contains 55 pts.  $\text{Na}_2\text{SO}_4$  for 100 pts.  $\text{H}_2\text{O}$ , but as the hydrous salt decreases in amount and becomes converted into the anhydrous salt, the solution becomes weaker and contains only 49.53 pts.  $\text{Na}_2\text{SO}_4$  for 100 pts.  $\text{H}_2\text{O}$  after warming for 6 or 8 hours at  $34^\circ$ . In the same way temporary solutions can be obtained at  $36-40^\circ$  with 55-56 pts.  $\text{Na}_2\text{SO}_4$  to 100 pts.  $\text{H}_2\text{O}$ , but this amount sinks to the normal even more quickly than at  $34^\circ$ .

$\text{Na}_2\text{SO}_4$  dehydrated at  $100-150^\circ$ , after the addition of  $1\frac{1}{2}-1\frac{1}{2}$  pts.  $\text{H}_2\text{O}$ , gives a solution between  $0^\circ$  and  $32^\circ$  of the same strength as  $\text{Na}_2\text{SO}_4 + 10\text{H}_2\text{O}$ , but at  $34^\circ$  a solution with

55 pts.  $\text{Na}_2\text{SO}_4$  to 100 pts.  $\text{H}_2\text{O}$  cannot be obtained, but one with 49.53 pts. is formed. (Löwel, A. ch. (3) 49. 32.)

Supersaturated solutions of  $\text{Na}_2\text{SO}_4$  are easily formed; when  $\text{Na}_2\text{SO}_4 + \text{Aq}$  sat. at its b-pt. is hermetically sealed, no crystals are deposited on cooling (Löwel). Supersat.  $\text{Na}_2\text{SO}_4 + \text{Aq}$  may also be obtained by cooling hot sat.  $\text{Na}_2\text{SO}_4 + \text{Aq}$  in flasks loosely stoppered with cotton wool (Schroeder, A. 106. 45), or by covering the containing vessel with a glass plate, watch-glass, card, etc., or by covering the liquid itself with a layer of oil, and then allowing to cool.

Hot  $\text{Na}_2\text{SO}_4 + \text{Aq}$  containing 1 pt.  $\text{H}_2\text{O}$  to 1 pt.  $\text{Na}_2\text{SO}_4 + 10\text{H}_2\text{O}$  does not crystallise on slowly cooling or on being quickly cooled by immersion in cold water, if it is contained in a barometer tube freed from air by boiling. or in an exhausted well-closed vessel, or in an open vessel with a layer of oil of turpentine on it (Gay-Lussac); or in a vessel containing air, either well stoppered or furnished with a loose cover (Schweigger); or in an open vessel under a bell jar full of air and closed at the bottom with a water joint; or in open bottles placed in a quiet situation; or in an open glass enclosed in a stoppered vessel, containing air and some KOH for drying; in this case  $\text{Na}_2\text{SO}_4 + 10\text{H}_2\text{O}$  effloresces from the solution, and when washed down again does not cause instant crystallisation, but redissolves.

The crystallisation of a solution cooled in this way may often be brought about instantaneously, or often again after a short time; (1) by agitation, when the solution has been cooled in an open vessel; (2) by access of air caused by opening the vessel, the crystallisation taking place the more rapidly the larger the opening. In this case the crystallisation begins at the top, where the solution, the vessel, and the air come in contact; when a particle of dust falls in the liquid the crystallisation begins a little under the surface. When the solution has been cooled in vacuo, a bubble of air, hydrogen, carbonic acid, or nitrous oxide is sufficient to set up the crystallisation; (3) by contact with a solid body. The latter do not cause crystallisation when cooled in contact with the liquid, nor (excepting a crystal of  $\text{Na}_2\text{SO}_4 + 10\text{H}_2\text{O}$ ) when they are moistened or warmed before contact with the solution.

Supersat.  $\text{Na}_2\text{SO}_4 + \text{Aq}$  is brought to crystallisation by addition of a crystal of  $\text{Na}_2\text{SO}_4 + 10\text{H}_2\text{O}$ , or an isomorphous substance as  $\text{Na}_2\text{SeO}_4 + 10\text{H}_2\text{O}$ , or  $\text{Na}_2\text{CrO}_4 + 10\text{H}_2\text{O}$ . Other crystals, as  $\text{MgSO}_4 + 7\text{H}_2\text{O}$ , etc., have no action. (Thomson, Chem. Soc. 35. 199.)

A more extended discussion of the phenomena and causes of supersaturation is not considered to be within the scope of this work.

At 33° and above the values represent the solubility of Na<sub>2</sub>SO<sub>4</sub> in NaCl+Aq. At 10° the solid phase in contact with the solution is probably Na<sub>2</sub>SO<sub>4</sub>·7H<sub>2</sub>O. Between 17° and 33° the solid phase is either Na<sub>2</sub>SO<sub>4</sub>·10H<sub>2</sub>O or Na<sub>2</sub>SO<sub>4</sub>. An inversion of Na<sub>2</sub>SO<sub>4</sub>·10H<sub>2</sub>O to Na<sub>2</sub>SO<sub>4</sub> takes place at various temp. below 33°, depending on the amount of NaCl contained in the solution in contact with the solid sodium sulphate.

(Seidell, Am. Ch. J. 1902, 27. 55.)

Sol. in sat. NH<sub>4</sub>NO<sub>3</sub>+Aq. (Marguerite, C. R. 38. 307.)

Sol. in sat. KNO<sub>3</sub>+Aq with pptn. after several hours. (Karsten.)

Na<sub>2</sub>SO<sub>4</sub>·10H<sub>2</sub>O is sol. in sat. NaNO<sub>3</sub>+Aq without pptn., but if effloresced Na<sub>2</sub>SO<sub>4</sub> is used, NaNO<sub>3</sub> is pptd. at first, and subsequently Na<sub>2</sub>SO<sub>4</sub>·7H<sub>2</sub>O.

The presence of CaSO<sub>4</sub> does not affect the solubility of Na<sub>2</sub>SO<sub>4</sub> in H<sub>2</sub>O to any great extent. (Barre, A. ch. 1911, (8) 24. 160.)

More sol. in K<sub>2</sub>SO<sub>4</sub>, CuSO<sub>4</sub>, MgSO<sub>4</sub>+Aq. than in H<sub>2</sub>O. (Pfaff, A. 99. 226.)

100 pts. H<sub>2</sub>O dissolve 20.7 pts. CuSO<sub>4</sub> and 15.9 pts. Na<sub>2</sub>SO<sub>4</sub>. (Rüdorff, B. 6. 484.)

Sol. in sat. MgSO<sub>4</sub>, K<sub>2</sub>SO<sub>4</sub>, CuSO<sub>4</sub>+Aq, but if more Na<sub>2</sub>SO<sub>4</sub> than can be dissolved is added to the CuSO<sub>4</sub>+Aq, a large quantity of a double sulphate separates out. (Karsten.)

The solubility of Na<sub>2</sub>SO<sub>4</sub> in K<sub>2</sub>SO<sub>4</sub>+Aq has been determined at 15°, 25°, 40°, 50°, 60°, 70° and 80°. From the results the conclusion is drawn that sodium and potassium sulphates form a double salt of the formula K<sub>2</sub>Na(SO<sub>4</sub>)<sub>2</sub>. (Okada, Chem. Soc. 1915, 108. (2) 344.)

See also under CuSO<sub>4</sub>, MgSO<sub>4</sub>, and K<sub>2</sub>SO<sub>4</sub>.

The solubility of the hydrates of  $\text{Na}_2\text{S}_2\text{O}_3$  are exceedingly complicated. There are five groups of hydrates, (I) primary, (II) secondary, (III) tertiary, (IV) quaternary, and (V), quintary, and transitions occur between members of the same and different groups.  $\text{Na}_2\text{S}_2\text{O}_3 + 5\text{H}_2\text{O}$  (I) is the commercial thiosulphate. The relations and solubility of the various hydrates is shown in the following table.

Slowly sol. in dil. cold  $HCl + Aq$ , but rapidly sol. if hot and conc. Slowly sol. in hot dil.  $H_2SO_4 + Aq$ , but decomp. by hot conc.  $H_2SO_4$ .

Readily sol. in cold aqua regia. Attacked violently by conc.  $HNO_3 + Aq$  with pptn. of  $SnO_2$ . Completely sol. in dil. cold  $HNO_3 + Aq$  (1 pt.  $HNO_3$ : 1 pt.  $H_2O$ ) at  $22^\circ$ . (Hay, C. N. **22**, 298.) Not attacked by pure conc.  $HNO_3 + Aq$  of 1.512–1.419 sp. gr., but violently attacked by less conc. acid. Also attacked by most conc. acid if it contains  $NO_2$ . (Millon, A. ch. (3) **6**, 95.)

If Sn is placed in dil.  $HNO_3 + Aq$  of 1.15 sp. gr. it is sl. dissolved, but soon pptd. again as  $SnO_2$ . If a small amt. of  $NH_4Cl$  is added, the Sn remains permanently in solution;  $HCl + Aq$  has a similar action. (Ordway, Am. J. Sci. (2) **23**, 220.) Easily sol. in the cold in mixture of 1 vol.  $H_2SO_4$ , 2 vols.  $HNO_3$ , and 3 vols.  $H_2O$ . (Basset, C. N. **53**, 172.)

$HNO_3 + Aq$  containing less than 12%  $HNO_3$  attacks Sn and forms a stannous salt, which decomposes, giving a turbid solution.  $HNO_3 + Aq$  (12–45%  $HNO_3$ ) completely dissolves Sn, but solution becomes turbid on standing.  $HNO_3 + Aq$  containing more than 45%  $HNO_3$  does not dissolve Sn, but forms a white substance, which is sol. in  $H_2O$  if over 70% acid is used; this solution soon becomes turbid. (Montemartini, Gazz. ch. it. **22**, 384.)

Sn dissolves in  $HNO_3 + Aq$  at low temps. ( $0$ – $21^\circ$ ). When very dil.  $HNO_3 + Aq$  (14%  $HNO_3$ ) is used, the amount of stannous salt formed decreases only slightly with increase of temp. while with 30–40% acid it falls to zero at  $21^\circ$ . (Walker, J. Soc. Chem. Ind. **1893**, 845.)

In presence of Fe, Cr or Al,  $HNO_3 + Aq$  acts on Sn to form soluble products, from which conc.  $HNO_3$  ppts. all Sn as meta-stannic acid. (van Leent, C. C. **1899**, I. 101.)

Much more sol. in acids when small quantities of metallic salts have been added. This is most noticeable when  $PtCl_4$  or tartar emetic is added to  $HCl + Aq$ .  $HCl + Aq$  with tartar emetic exerts 11 times, and with  $PtCl_4$  13 times the action exhibited by pure acid. (Millon, C. R. **21**, 47.)

Sol. in 2N  $HClO_3 + Aq$ . (Hendrixson, J. Am. Chem. Soc. 1904, **26**, 755.)

**Tin (stannic) hydroxide.**

" $\alpha$ " modification.

Obtained by pptn. by alkali in stannic chloride solution.

Freshly pptd. substance when air dried contains 73.5%  $\text{H}_2\text{O}$ ; when dried over  $\text{H}_2\text{SO}_4$  or in a vacuum for 1 month 12.6%  $\text{H}_2\text{O}$ . Heated to glowing loses all  $\text{H}_2\text{O}$  and passes into the anhydride. The " $\alpha$ " form is capable of existing in all degrees of hydration. (Lorenz, Z. anorg. 1895, 9. 372-375.)

" $\alpha$ " stannic hydrate is a white amorphous substance which is very sol. in  $\text{HNO}_3$  when moist; sol. in  $\text{H}_2\text{SO}_4$  even dil.; sol. in  $\text{HCl}$  and not pptd. by an excess. Very sol. in  $\text{NaOH}$  + Aq. and is not pptd. by an excess.

A solution of  $\alpha$  stannic acid in  $\text{HCl}$  is identical with a solution of freshly prepared aqueous stannic chloride and gives no ppt. with dil.  $\text{HCl}$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{HNO}_3$  or arsenic acid even on long standing.

" $\beta$ " modification.

Obtained by oxidizing and dissolving Sn in  $\text{HNO}_3$ , and from solution of sodium stannate by pptn. Freshly pptd. from  $\text{HNO}_3$  when air dried contains 21.3%  $\text{H}_2\text{O}$ , and when dried over  $\text{H}_2\text{SO}_4$  or in a vacuum 11.3%,—corresponding to  $\text{Sn}(\text{OH})_4$  and  $\text{SnO}(\text{OH})_2$ , respectively.

Freshly pptd. from sodium stannate solution and air dried contains 22.5%  $\text{H}_2\text{O}$  and when dried over  $\text{H}_2\text{SO}_4$  or in a vacuum contains 12.1%,—corresponding to  $\text{Sn}(\text{OH})_4$  and  $\text{SnO}(\text{OH})_2$ . Passes into the anhydride when heated to glowing.

The " $\beta$ " form is capable of existing in all degrees of hydration. It is a white amorphous substance which is insol. in  $\text{HNO}_3$ ; in-

sol. in  $\text{H}_2\text{SO}_4$  even when conc.; insol. in  $\text{HCl}$  but changed by contact with the acid in that when the acid has been removed the ppt. is readily sol. in  $\text{H}_2\text{O}$ , though pptd. again from solution by addition of  $\text{HCl}$ . When freshly prepared the " $\beta$ " form is sol. in  $\text{NaOH}$  + Aq. but is pptd. by an excess of  $\text{NaOH}$ .

A solution of " $\beta$ " stannic acid in  $\text{HCl}$  behaves quite differently from an aq. solution of stannic chloride in that it ppts. metastannic sulphate when treated with  $\text{H}_2\text{SO}_4$ .

This ppt. dissolves when heated with dilute  $\text{HNO}_3$  or  $\text{HCl}$ , but the solution on standing spontaneously forms another ppt. A solution of " $\beta$ " stannic acid in  $\text{HCl}$  gives a ppt. when treated with arsenic acid. (Lorenz, Z. anorg. 1895, 9. 372.)

60.1 grams anhydrous salt are sol. in 100 grams of abs. alcohol at 15°.

6.5 grams are sol. in 100 grams pyridine. (Matignon, A. ch. 1906, (8) **8**, 437.)**Yttrium fluoride,  $YF_3 + \frac{1}{2}H_2O$ .**

Not attacked by pure cold  $H_2O$ . Slowly oxidised by boiling  $H_2O$ . Pure  $H_2O$  free from  $O$  dissolved nothing from 2500 sq. mm. Zn. Presence of air containing  $CO_2$  caused a solution of 3.5 mg. Zn, which maximum was reached in 2 days. Air without  $CO_2$  also caused a slight action. (Snyders, B. **11**, 936.)

100 ccm. distilled  $H_2O$  dissolved 14 mg. Zn from 11.8 sq. cm. in one week, during which air free from  $CO_2$  was passed through the liquid, and 19 mg. when air containing  $CO_2$  was used. (Wagner, Dingl. **221**, 260.)

Filtered rain water was found to contain 20 mg. Zn per l. (Burg, Isis, **1873**, 119.)

Very pure  $H_2O$ , when conducted through a great length of galvanized iron pipe, contained 1.7 pts. Zn to 100,000 pts.  $H_2O$ . (Davies, J. Soc. Chem. Ind. **1899**, **18**, 102.)

Action of  $H_2O$  on Zn in galvanized pipes is caused by electrolysis. (Smetham, C. N. **1879**, **39**, 236.)

All kinds of  $H_2O$  attack Zn, rain water the least.

In distilled  $H_2O$  exposed to air Zn is abund-

dantly coated with  $\text{ZnCO}_3$ ,  $2\text{ZnO} + 3\text{H}_2\text{O}$ . By allowing 32 g. Zn to stand in 270 cc. distilled  $\text{H}_2\text{O}$  in a flask loosely stoppered with filter paper, 1.2 pts. Zn to 100,000 pts.  $\text{H}_2\text{O}$  was found in solution in 1-2 days. (Smith, J. Soc. Chem. Ind. 1904, 23, 475.)

Sol. in all acids. Very slowly sol. in dil.  $\text{HCl}$  or  $\text{H}_2\text{SO}_4 + \text{Aq}$  in glass vessels if Zn is pure. According to Jacquelin, 24 hours were necessary to dissolve 6 g. pure zinc. When fused at the lowest possible temperature, it is much more slowly sol. than when heated to a red heat. In both cases it is much more rapidly dissolved if cooled quickly. (Bolley, A. 95, 294; Rammelsberg.)

Dil.  $\text{H}_2\text{SO}_4 + \text{Aq}$  dissolves given % zinc in the same length of time (B=according to Bolley, R=according to Rammelsberg):

(Calvert and Johnson, Chem. Soc. 19, 437.)

C. P. zinc is more quickly sol. in dil. acids in vacuo than under normal pressure, the ratio being about 1:6.5. The rate of solubility increases slowly with rise of temp. from  $0^\circ$  to  $98^\circ$ , when it amounts to about 4 times that at  $0^\circ$ , but from  $98^\circ$ – $100^\circ$  the increase is thirteenfold. Thus, as an average of 6 experiments, dil.  $\text{H}_2\text{SO}_4 + \text{Aq}$  (1:20) dissolves in 30 minutes 2.1 mg. Zn at  $0^\circ$ ; 4.9 mg. at  $20^\circ$ ; 7.4 mg. at  $60^\circ$ ; 9.3 mg. at  $98^\circ$ ; but 122.1 mg. at  $100^\circ$ . If, however, the acid was prevented from boiling by increasing the pressure, the sudden increase between  $98^\circ$  and  $100^\circ$  does not take place.

The rate of solubility in dil.  $\text{H}_2\text{SO}_4 + \text{Aq}$  (1:20) is also increased 175 times by the addition of  $\text{CrO}_3$  and 306 times by the addition of  $\text{H}_2\text{O}_2$ . The above phenomena are explained by assuming the formation of a condensed hydrogen atmosphere around the metal, which prevents the further action of the acid. (Weeren, B. 24, 1785.)

Not attacked by  $\text{HNO}_3 + \text{Aq}$  of 1.512 to 1.419 sp. gr. at a temp. of  $-18^\circ$  or less, but violently attacked if temp. is raised.  $\text{HNO}_3 + \text{Aq}$  of 1.419–1.401 sp. gr. does not attack Zn at temp. of a freezing mixture, but violently at  $0^\circ$ . More dil.  $\text{HNO}_3 + \text{Aq}$  attacks Zn even at  $-20^\circ$ . (Millon, A. ch. (3) 6, 99.)

Sol. in  $\text{H}_2\text{CO}_3 + \text{Aq}$ . (Berzelius.)

Solubility of Zn in acids is very much affected by the presence of small quantities of various metallic salts. Small amts. of  $\text{PtCl}_4 + \text{Aq}$  accelerated the action of  $\text{H}_2\text{SO}_4 + \text{Aq}$  149 times, and  $\text{As}_2\text{O}_3$  123 times.  $\text{HgCl}_2$  has a strong retarding action owing to pptn. of Hg on the Zn.

The rate of solution of Zn in acids and the effect of changes in concentration and temperature and of the presence of inorganic salts and organic substances on this rate has been studied. 26 Tables are given. (Ericson-Aurén, Z. anorg. 1901, 27, 209–253.)

Speed of solution in  $\text{H}_2\text{SO}_4$  and in  $\text{HCl}$  (Centnerszwer, Z. phys. Ch. 1914, 87, 692.)

Various saline solutions have a strong solvent power in presence of  $\text{PtCl}_4$ , i.e.  $\text{KCl}$ ,  $\text{NaCl}$ ,  $\text{Na}_2\text{SO}_4$ ,  $\text{K}_2\text{SO}_4$ ,  $\text{MgSO}_4 + \text{Aq}$ .  $\text{PtCl}_4$  also causes Zn to decompose distilled  $\text{H}_2\text{O}$ .  $\text{CuSO}_4$  has a similar but less energetic effect.

In all the above cases the disengagement of hydrogen is slower in the dark than in the light. (Millon, C. R. 21, 37.)

According to Barreswill (C. R. 21, 292) the above reactions are all caused by galvanic action due to pptd. metal, and a piece of Pt in contact with the Zn causes the same action as the  $\text{PtCl}_4$  in solution.

Easily sol. in alkalis + Aq, even  $\text{NH}_4\text{OH} + \text{Aq}$ , especially when the Zn is in contact with Fe. Sol. in  $\text{NaCl} + \text{Aq}$  with pptn. of  $\text{ZnO}$ . (Siersch, J. B. 1867, 257.)

Sol. in sat. alkali and alkali-earth chlorides + Aq. (Post, 1872.)

Sol. in  $\text{NH}_4$  salts + Aq. (Lorin, J. B. 1865, 124.)

Sol. in sat.  $\text{Na}_2\text{SO}_4$ ,  $\text{K}_2\text{SO}_4$ ,  $\text{MgSO}_4$ ,  $\text{NaNO}_3$ ,  $\text{KNO}_3$ ,  $\text{Ba}(\text{NO}_3)_2$ ,  $\text{CaCl}_2$ ,  $\text{MgCl}_2$ , and  $\text{NH}_4\text{NO}_3 + \text{Aq}$ . Chlorides and sulphates (especially  $\text{Na}_2\text{SO}_4$  and  $\text{MgCl}_2$ ) have strongest action,  $\text{MgSO}_4$  and nitrates the least. The action was greatly increased by heat. (Snyders, B. 11, 936.)

Sol. in boiling  $\text{NH}_4\text{Cl} + \text{Aq}$ . Sol. in neutral  $\text{FeCl}_2 + \text{Aq}$  with pptn. of Fe, especially easily at  $100^\circ$ . (Capitaine, C. R. 9, 737.)

Sol. in  $\text{NiSO}_4 + \text{Aq}$  with pptn. of  $\text{NiO}$ . (Tupputi.)

Sol. in conc. hot  $\text{ZnCl}_2 + \text{Aq}$ , but Zn oxy-

chloride is pptd. on diluting. (Ordway, Am. J. Sci. (2) **23**, 222.)

Sol. in  $\text{GISO}_4$ +Aq. (Debray.)

(Grüger, Z. anorg. 1911, 70. 136.)

When moist is easily sol. in  $\text{KOH}$ ,  $\text{NaOH}$ , and  $\text{NH}_4\text{OH} + \text{Aq}$ , but only sl. sol. therein after ignition. Partially reprecipitated from solution in  $\text{NH}_4\text{OH} + \text{Aq}$  by dilution with  $\text{H}_2\text{O}$ .

Anhydrous  $\text{ZnO}$  is insol. in dil., but sol. in conc. alkali hydrates +  $\text{Aq}$ , but the hydroxide is easily sol. even in dil. alkalis +  $\text{Aq}$ . (Fremy, A. ch. (3) 23. 390.)

Very sl. sol. in  $\text{NH}_4\text{OH} + \text{Aq}$ . After igni-

tion its solubility is greatly increased by traces of  $\text{K}$  and  $\text{NH}_4$  salts. Phosphates have the strongest action, then, in the following order: arsenates, chlorides, sulphites, nitrates, acetates, carbonates, tartrates, citrates, and sulphates. Succinates and benzoates increase the solubility in  $\text{NH}_4\text{OH} + \text{Aq}$ , only when it is very dil.; borates, iodides, chlorates, arsenites, gallates, and oxalates do not increase the solubility. (Schindler.)

$\text{ZnO}$  is sol. in  $\text{NH}_4\text{OH} + \text{Aq}$ . only in presence of  $\text{NH}_4$  salts. (Brandhorst, Zeit. angew. Ch. 1904, 17. 513.)

Solubility in  $\text{KOH}$ ,  $\text{NaOH}$ , and  $\text{NH}_4\text{OH} + \text{Aq}$ .

An excess over 4 mols.  $\text{KOH}$  to 1 mol.  $\text{ZnO}$  is necessary for solution, but that excess may be neutralised after solution, until only 4 mols. are left, without pptn. of  $\text{ZnO}$ . Solution is pptd. by addition of 12 vols.  $\text{H}_2\text{O}$ .  $\text{KOH} + \text{Aq}$  containing 16.5 g.  $\text{KOH}$  to a litre  $\text{H}_2\text{O}$  is the weakest solution which will dissolve  $\text{ZnO}$ . Three times as much alkali are necessary for solution at  $50^\circ$  as at  $16-17^\circ$ . Less excess of  $\text{NaOH}$  than of  $\text{KOH}$  is necessary. 3 mols.  $\text{NH}_4\text{OH}$  will dissolve 1 mol.  $\text{ZnO}$ , and the temp. and dilution are in this case of little influence. (Prescott.)

100 cc. of 20%  $\text{NaOH} + \text{Aq}$  dissolve in many hours at most 2.97 g. ignited  $\text{ZnO}$ . Pptd.  $\text{ZnO}$  is more quickly dissolved but the action becomes very slow after 100 cc. of the solution contain 3.87 g. of  $\text{Zn}$ . (Förster and Günther, Z. Elektrochem. 1900, 6. 301.)

Solubility of ignited  $\text{ZnO}$  in  $\text{NaOH} + \text{Aq}$  gradually decreases. (Kunschert, Z. anorg. 1904, 41. 343.)

Sol. in hot  $\text{NH}_4\text{Cl} + \text{Aq}$ , either when moist or dry.

Somewhat less sol. in  $\text{NH}_4\text{NO}_3 + \text{Aq}$ .

Somewhat sol. in water glass +  $\text{Aq}$ . (Ordway.)

Slowly sol. in cold, easily in hot  $\text{NaCl} + \text{Aq}$ . (Siersch, J. B. 1867. 255.)

The solubility curve has a maximum at a point corresponding to about 125 g.  $\text{ZnCl}_2$  per 100 g.  $\text{H}_2\text{O}$ . On the first branch of the curve the solid phase in equilibrium with the solution is  $\text{ZnCl}_2, 4\text{ZnO}, 6\text{H}_2\text{O}$ ; on the second branch it is  $\text{ZnCl}_2, \text{ZnO}, 1.5\text{H}_2\text{O}$ .
